

Question #1 of 79

Question ID: 1473389

7.5%, 15-year, annual pay option-free Xeleon Corp bond trades at a market price of \$95.72 per \$100 par. The government spot rate curve is flat at 5%.

Suppose that the Xeleon bond was callable in 10 years at par and an analyst computed the Z-spread on the bond ignoring the embedded option. Relative to the Z-spread on an option-free bond, the calculated Z-spread will *most likely* be:

A) the same.

B) higher.

C) lower.

Explanation

Since a bond with an embedded call option would trade at a lower price than a comparable option-free bond (i.e., its market price would be lower), the additional spread needed to force the model value to the (lower) market price will be higher. Because the Z-spread would inadvertently include compensation for option risk as well as for credit and liquidity risks, it is not appropriate for valuing bonds with embedded options.

(Module 25.4, LOS 25.g)

Question #2 of 79

Question ID: 1473378

Which one of the following is *least likely* a reason to use the swap rate curve?

A) The swap market is not regulated by any government.

B) Swap rates reflect credit risk of commercial banks and not government.

C) Swap rates are less volatile than government bond yields.

Explanation

Lower volatility of swap rates relative to government bond yields as a generalization is an incorrect statement.

(Module 25.3, LOS 25.e)

Question #3 of 79

Question ID: 1473392

Credit risk in the banking system is most accurately captured by the:

A) I-spread.

B) 10-year swap spread.

C) TED spread.

Explanation

Comparing the TED spread with the 10-year swap spread, the TED spread more accurately reflects the risk in the banking system, while the 10-year swap spread mostly reflects differing supply and demand conditions. An I-spread refers to a bond yield net of the swap rate of the same maturity.

(Module 25.4, LOS 25.g)

Question #4 of 79

Question ID: 1473403

Jim Malone, CIO of Sigma bond fund had a successful track record of investing in investment grade bonds. Recently though, Sigma has been lagging its peers because Malone refuses to reduce the duration of the portfolio by purchasing short-term bonds for the fund. Malone's actions are *most consistent* with:

- A) Liquidity preference theory.
- B) Segmented markets theory.
- C) Preferred habitat theory.

Explanation

Under segmented markets theory investors in one maturity segment of the market will not move into any other maturity segments.

(Module 25.5, LOS 25.h)

Question #5 of 79

Question ID: 1473416

Suppose that the short-term and long-term rates decrease by 75bps while the intermediate-term rates decrease by 30bps. The movement in yield curve is *best* described as involving changes in the:

- A) level only.
- B) level and curvature.
- C) curvature only.

Explanation

The decrease in short-term and long-term rates is an indication of change in level of interest rates. Because intermediate-term rates change differently than the short-term and long-term rates, there is also a change in the curvature of the yield curve.

(Module 25.6, LOS 25.i)

Question #6 of 79

Question ID: 1473368

Jorgen Welsher, CFA obtains the following quotes for zero coupon government bonds all with a par value of \$100.

Type of Price	Delivery (years)	Maturity (years)	Price
Spot	0	3	\$91.51
Forward	2	3	\$94.55
Spot	0	2	\$92.45

Welsher can earn arbitrage profits by:

- A) buying the 2-year bond in the spot market, going long the forward contract and selling the 3-year bond in the spot market. 
- B) buying the 2-year bond in the spot market, going short the forward contract and selling the 3-year bond in the spot market. 
- C) selling the 2-year bond in the spot market, going short the forward contract and buying the 3-year bond in the spot market. 

Explanation

$F_{(2,1)} = P_3/P_2 = \$98.98$ but is quoted at \$94.55 and hence is cheap – buy it. A combination of a long position in the 2-year spot market, rolled over for 1 year at a locked-in forward rate (i.e., a long position in forward), would generate a return higher than the quoted 3-year spot rate.

(Module 25.1, LOS 25.a)

Question #7 of 79

Question ID: 1473422

Rising inflation when the economy is expanding could *most likely* lead to a:

- A) bearish flattening. 
- B) bearish steepening. 
- C) bullish steepening. 

Explanation

During expansionary times, to combat rising inflation, central banks may raise short-term rates leading to a bearish flattening of the yield curve.

(Module 25.6, LOS 25.k)

Question #8 of 79

Question ID: 1473401

Which theory explains the shape of the yield curve by considering the relative demands for various maturities?

- A) The pure expectations theory. 
- B) The segmentation theory. 

C) The liquidity premium theory.

Explanation

The market segmentation theory contends that lenders and borrowers have preferred maturity ranges, and that supply and demand forces in each maturity range determines yields. This theory relies on the idea that some investors have restrictions (either legal or practical) on their preferred maturity structure and that they are unwilling or unable to move out of their preferred ranges.

(Module 25.5, LOS 25.h)

Carol Stephens, CFA, oversees five portfolio managers who all manage fixed income portfolios for one institutional client. Stephens feels that interest rates will change over the next year but is uncertain about the extent and direction of this change. She is confident, however, that the yield curve will change in a nonparallel manner and that modified duration will not accurately measure the overall total portfolio's yield-curve risk exposure. To help her evaluate the risk of her client's total portfolio, she has assembled the table of rate durations shown below.

Issue	Value (\$millions)	3 mo	2 yr	5 yr	10 yr	15 yr	20 yr	25 yr	30 yr
Portfolio 1	100	0.03	0.14	0.49	1.35	1.71	1.59	1.47	4.62
Portfolio 2	200	0.02	0.13	1.47	0.00	0.00	0.00	0.00	0.00
Portfolio 3	150	0.03	0.14	0.51	1.40	1.78	1.64	2.34	2.83
Portfolio 4	250	0.06	0.00	0.00	0.00	0.00	0.00	0.00	0.00
Portfolio 5	300	0.00	0.88	0.00	0.00	1.83	0.00	0.00	0.00

The value of the total portfolio is \$1,000,000,000.

Question #9 - 12 of 79

Question ID: 1586238

For this question only, imagine that the original yield curve undergoes a parallel shift such that the rates at all key maturities increase by 50 basis points. The new value of the total portfolio will be *closest* to:

A) \$980,537,500.

B) \$1,019,462,500.

C) \$961,075,000.

Explanation

Key Rate Durations										
	weight	3 mo	2 yr	5 yr	10 yr	15 yr	20 yr	25 yr	30 yr	Effective Duration
Portfolio 1	0.10	0.03	0.14	0.49	1.35	1.71	1.59	1.47	4.62	11.40
Portfolio 2	0.20	0.02	0.13	1.47	0.00	0.00	0.00	0.00	0.00	1.62
Portfolio 3	0.15	0.03	0.14	0.51	1.40	1.78	1.64	2.34	2.83	10.67
Portfolio 4	0.25	0.06	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.06
Portfolio 5	0.30	0.00	0.88	0.00	0.00	1.83	0.00	0.00	0.00	2.71
Total Portfolio	1.00	0.0265	0.3250	0.4195	0.3450	0.9870	0.4050	0.4980	0.8865	3.8925

Since the yield curve underwent a parallel shift, the impact on portfolio value can be computed directly using the portfolio's effective duration. There are two methods that can be used to calculate effective duration in this situation. Both methods use the market weight of the individual bonds in the portfolio. As shown in the second column of the table above, the total portfolio weight of each subportfolio equals: Bond value/Portfolio value, where the portfolio value is \$1,000,000,000.

Method 1) Effective duration of the portfolio is the sum of the weighted averages of the key rate durations for each issue. The 3-month key rate duration for the total portfolio can be calculated as follows:

$$(0.10)(0.03) + (0.20)(0.02) + (0.15)(0.03) + (0.25)(0.06) + (0.30)(0) = 0.0265$$

This method can be used to generate the rest of the key rate duration shown in the bottom row of the table above and summed to yield an effective duration = 3.8925.

Method 2) Effective duration of the portfolio is the weighted average of the effective durations for each issue. The effective duration of each issue is the sum of the individual rate durations for that issue. These values are shown in the right-hand column of the table above. Using this approach, the effective duration of the portfolio can be computed as:

$$(0.10)(11.4) + (0.20)(1.62) + (0.15)(10.67) + (0.25)(0.06) + (0.30)(2.71) = 3.8925$$

Using an effective duration of 3.8925, the value of the portfolio following a parallel 50 basis point shift in the yield curve can be computed as follows: Percentage change = (50 basis points)(3.8925) = 1.9463% decrease. $\$1,000,000,000 \times (1 - 0.0194625) = \$980,537,500$.

(Module 25.6, LOS 25.i)

Question #10 - 12 of 79

Question ID: 1586239

For this question only, imagine that the original yield curve undergoes a shift such that 3-month rates remain constant and all other rates increase by 135 basis points. The new value of portfolio 4 will be *closest* to:

- A) \$243,375,000.
- B) \$229,750,000.
- C) \$250,000,000.

Explanation

Key Rate Durations										
	weight	3 mo	2 yr	5 yr	10 yr	15 yr	20 yr	25 yr	30 yr	Effective Duration
Portfolio 1	0.10	0.03	0.14	0.49	1.35	1.71	1.59	1.47	4.62	11.40
Portfolio 2	0.20	0.02	0.13	1.47	0.00	0.00	0.00	0.00	0.00	1.62
Portfolio 3	0.15	0.03	0.14	0.51	1.40	1.78	1.64	2.34	2.83	10.67
Portfolio 4	0.25	0.06	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.06
Portfolio 5	0.30	0.00	0.88	0.00	0.00	1.83	0.00	0.00	0.00	2.71
Total Portfolio	1.00	0.0265	0.3250	0.4195	0.3450	0.9870	0.4050	0.4980	0.8865	3.8925

Since the 3-month rate did not change, and all other key rate durations for Portfolio 4 are zero, a 135 basis point change will have no effect on the value of Portfolio 4. Hence, Portfolio 4 remains valued at \$250,000,000.

(Module 25.6, LOS 25.i)

Question #11 - 12 of 79

Question ID: 1586240

The 10-year key rate duration for the total portfolio is *closest* to:

- A) 1.350.
- B) 0.345.
- C) 1.375.

Explanation

Key Rate Durations										
	weight	3 mo	2 yr	5 yr	10 yr	15 yr	20 yr	25 yr	30 yr	Effective Duration
Portfolio 1	0.10	0.03	0.14	0.49	1.35	1.71	1.59	1.47	4.62	11.40
Portfolio 2	0.20	0.02	0.13	1.47	0.00	0.00	0.00	0.00	0.00	1.62
Portfolio 3	0.15	0.03	0.14	0.51	1.40	1.78	1.64	2.34	2.83	10.67
Portfolio 4	0.25	0.06	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.06
Portfolio 5	0.30	0.00	0.88	0.00	0.00	1.83	0.00	0.00	0.00	2.71
Total Portfolio	1.00	0.0265	0.3250	0.4195	0.3450	0.9870	0.4050	0.4980	0.8865	3.8925

The total portfolio key rate duration for a specific maturity is the weighted value of the key rate durations of the individual issues for that maturity. In this case, the 10-year key rate duration for the portfolio is:

$$(0.10)(1.35) + (0.20)(0.00) + (0.15)(1.40) + (0.25)(0.00) + (0.30)(0.00) = 0.345$$

(Module 25.6, LOS 25.i)

Question #12 - 12 of 79

Question ID: 1586241

The effective duration for Portfolio 2 is *closest* to:

- A) 1.47.
- B) 0.023.
- C) 1.62.

Explanation

Key Rate Durations										
	weight	3 mo	2 yr	5 yr	10 yr	15 yr	20 yr	25 yr	30 yr	Effective Duration
Portfolio 1	0.10	0.03	0.14	0.49	1.35	1.71	1.59	1.47	4.62	11.40
Portfolio 2	0.20	0.02	0.13	1.47	0.00	0.00	0.00	0.00	0.00	1.62
Portfolio 3	0.15	0.03	0.14	0.51	1.40	1.78	1.64	2.34	2.83	10.67
Portfolio 4	0.25	0.06	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.06
Portfolio 5	0.30	0.00	0.88	0.00	0.00	1.83	0.00	0.00	0.00	2.71
Total Portfolio	1.00	0.0265	0.3250	0.4195	0.3450	0.9870	0.4050	0.4980	0.8865	3.8925

The effective duration for any individual issue is the sum of the individual key rate durations for that issue. For Portfolio 2, the effective duration is:

$$0.02 + 0.13 + 1.47 = 1.62$$

(Module 25.6, LOS 25.i)

Question #13 of 79

Question ID: 1473387

7.5%, 15-year, annual pay option-free Xeleon Corp bond trades at a market price of \$95.72 per \$100 par. The government spot rate curve is flat at 5%.

The Z-spread on Xeleon Corp bond is *closest* to:

- A) 300 bps
- B) 325 bps
- C) 250 bps

Explanation

Since the spot rate curve is flat, we can simply compute the yield on the bond and subtract the spot rate from it to obtain the Z-spread.

$$PV = -95.72; N = 15; PMT = 7.50; FV = 100; I/Y = ? = 8\%$$

$$Z\text{-spread} = 8\% - 5\% = 3\% \text{ or } 300\text{bps}$$

(Module 25.4, LOS 25.g)

Question #14 of 79

Question ID: 1473423

To jump start a sluggish economy could *most likely* lead to a:

- A) bullish steepening.
- B) bearish flattening.

C) bearish steepening.

Explanation

During recessionary times, central banks may reduce short-term rates leading to a bullish steepening.

(Module 25.6, LOS 25.k)

Question #15 of 79

Question ID: 1473418

A bond portfolio has the following key rate durations:

$$D_2 = 0.50; D_5 = 2.70 \text{ and } D_{15} = 7.23.$$

Suppose that the change in yield curve results in changes in the following par rates:

$$p_1 = +50\text{bps}; p_2 = +100\text{bps}; p_5 = +25 \text{ bps}; p_{10} = -75\text{bps}; p_{15} = -100\text{bps}.$$

The change in the value of the portfolio will be *closest* to:

A) 6.06%

B) -2.80%

C) 4.75%

Explanation

$$\% \Delta P = -(0.50)(1.0) - (2.70)(0.25) - (7.23)(-1) = 6.06\%$$

(Module 25.6, LOS 25.i)

Question #16 of 79

Question ID: 1473377

Independence Bank is a small retail bank that specializes in demand deposits and invests in CMO tranches. For the purpose of valuation of Independence Bank's assets and liabilities, the *most appropriate* reference yield curve would be:

A) MRR-OIS curve.

B) government spot curve.

C) swap rate curve.

Explanation

While wholesale banks extensively hedge their assets and/or liabilities using the swap market, retail banks typically have very little exposure to the swap market. Accordingly, the government spot curve is most appropriate for retail banks while the swap rate curve may be most appropriate for wholesale banks.

(Module 25.3, LOS 25.e)

Question #17 of 79

Question ID: 1473393

Under the liquidity preference theory, expected future spot rates will *most likely* be:

- A) More than the current forward rate.
- B) Less than the current forward rate.
- C) Equal to the current forward rate.

**Explanation**

Existence of a liquidity premium under the liquidity preference theory implies that the current forward rate is an upwardly biased estimate of the future spot rate.

(Module 25.5, LOS 25.h)

Question #18 of 79

Question ID: 1473362

If the 2-year spot rate is 4% and 1-year spot rate is 7%, the one year forward rate one year from now is *closest* to:

- A) 2%
- B) 1%
- C) 3%

**Explanation**

$$(1+S_2)^2 = (1+s_1)[1+f(1,1)]$$

$$f(1,1) = (1.04)^2 / (1.07) - 1 = 0.0108 = 1.08\%$$

(Module 25.1, LOS 25.a)

Question #19 of 79

Question ID: 1473386

The swap spread will increase with:

- A) a deterioration in one party's credit.
- B) the variability of interest rates.
- C) an increase in the credit spread embedded in the reference.

**Explanation**

The swap spread is the spread between the fixed-rate on a market-rate swap and the Treasury rate on a similar maturity note/bond. Since the fixed rate is calculated from the reference rate yield curve, it is increased as the credit spread embedded in the reference rate yield curve increases.

(Module 25.4, LOS 25.f)

James Wallace, CFA, is a fixed income fund manager at a large investment firm. Each year, the firm recruits a group of new college graduates in the spring to enter in the firm's management training program. The program

is a rigorous six-month course that exposes every candidate to each of the different departments within the firm. After successfully completing the six-month training period, candidates then receive offers for employment in one of the departments within the investment firm. Recently, Wallace was selected by his boss to teach the fixed income portion of the firm's training program. He will be able to hold several two-hour sessions with the new hires over a two-week time period, during which he is expected to instruct the trainee's on all aspects of fixed income analysis. These sessions serve as preparation for the trainees to be able to complete a month long rotation on the fixed income trading desk.

His first few sessions will cover the core concepts of fixed income investing. Wallace believes that in order to fully grasp the more complicated concepts of fixed income analysis, the new hires must first begin by having a complete knowledge of the term structure and the volatility of interest rates. The new hires each have different educational backgrounds and varying amounts of work experience, so Wallace decides to begin with the most very basic concepts. He wants to start by teaching the various theories of the term structure of interest rates, and the implications of each theory for the shape of the Treasury yield curve. To evaluate the trainees' understanding of the subjects at hand, he creates a series of questions.

The following interest rate scenario is used to derive examples on the different theories used to explain the shape of the term structure and for all computational problems in Wallace's lectures.

Table 1 LIBOR Forward Rates and Implied Spot Rates

Period	LIBOR Forward Rates	Implied Spot Rates
0 × 6	5.0000%	5.0000%
6 × 12	5.5000%	5.2498%
12 × 18	6.0000%	5.4996%
18 × 24	6.5000%	5.7492%
24 × 30	6.7500%	5.9490%
30 × 36	7.0000%	6.1238%

James uses a rounded day count of 0.5 years for each semi-annual period.

Question #20 - 23 of 79

Question ID: 1586233

Following Wallace's first lecture he asks the trainees which of the following explains an upward sloping yield curve according to the (unbiased) pure expectations theory of the term structure of interest rates?

- A) There is greater demand for short-term securities than for long-term securities. 
- B) There is a risk premium associated with more distant maturities. 
- C) The market expects short-term rates to rise through the relevant future. 

Explanation

Under this theory, forward rates exclusively represent expected future spot rates. Thus the entire term structure at a given time reflects the market's expectations of future short term spot rates.

(Module 25.5, LOS 25.h)

Question #21 - 23 of 79

Question ID: 1586234

Wallace now poses a similar question regarding the liquidity preference theory. Which of the following could explain an upward sloping yield curve according to the liquidity preference theory of the term structure of interest rates?

- A) There is a risk premium associated with more distant maturities. 
- B) The market expects short-term rates to rise through the relevant future. 
- C) There is greater demand for short-term securities than for long-term securities. 

Explanation

According to the liquidity preference theory, the pure expectations theory applies but is modified for a risk or term premium. The longer the maturity, the greater the risk of price fluctuation to the investor.

Short-term rates to rise through the relevant future could explain an upward sloping yield curve according to the pure expectations theory. Greater demand for short-term securities than for long-term securities could explain an upward sloping yield curve according to the market segmentation theory. The market segmentation theory implies that the rate of interest for a particular maturity is determined solely by demand and supply for that maturity, with no reference to conditions for other maturities.

(Module 25.5, LOS 25.h)

Question #22 - 23 of 79

Question ID: 1586235

Wallace presents the relationships between spot and forward rates according to the pure expectations theory. Which of the following is *closest* to the one-year implied forward rate one year from now?

- A) 6.25%. 
- B) 6.58%. 
- C) 5.75%. 

Explanation

$$f(1,1) = (1+S_2)^2 / (1+S_1) - 1 = (1.057492)^2 / (1.052498) - 1 = 0.0625 \text{ or } 6.25\%$$

(Module 25.5, LOS 25.h)

Question #23 - 23 of 79

Question ID: 1586236

Wallace completes his first lecture by tying the relationship between Treasury prices and the shape of the term structure. He is particularly interested in the implications of a steepening yield curve. Which of the following is *most* accurate for a steepening yield curve?

- A) The price of short-term Treasury securities increases relative to the price of long-term Treasury securities. 

- B) The price of long-term Treasury securities increases relative to the price of short-term Treasury securities. 
- C) The price of short-term Treasury securities increases. 

Explanation

For a steepening of the yield curve to occur, in every case, the short-term yield has to decrease relative to the long-term yield. Therefore, the price of short-term Treasury securities increases relative to the price of long-term securities.

(Module 25.5, LOS 25.h)

Question #24 of 79

Question ID: 1473400

Don McGuire, fixed income specialist at MCB bank makes the following statement: "In the very short-term, the expected rate of return from investing in any bond, including risky bonds, is the risk-free rate of return".

McGuire's statement is *most* consistent with:

- A) unbiased expectations theory. 
- B) local expectations theory. 
- C) liquidity preference theory. 

Explanation

Local expectations theory asserts that in the very short term, the expected return for every bond is the risk-free rate but does not extend the risk-neutrality assumption to every maturity strategy like the unbiased expectations theory.

(Module 25.5, LOS 25.h)

Question #25 of 79

Question ID: 1473384

A swap spread is the difference between:

- A) the fixed rate on an interest rate swap and the rate on a Treasury bond of maturity equal to that of the swap. 
- B) the fixed-rate and floating-rate payment rates at the inception of the swap. 
- C) MRR and the fixed rate on the swap. 

Explanation

A swap spread is the difference between the fixed rate on an interest rate swap and a Treasury bond of maturity equal to that of the swap.

(Module 25.4, LOS 25.f)

Question #26 of 79

Question ID: 1473404

The liquidity theory of the term structure of interest rates is a variation of the pure expectations theory that explains why:

- A) the yield curve usually slopes downward.
- B) duration is an imprecise measure.
- C) the yield curve usually slopes upward.

Explanation

The pure expectations hypothesis says that the shape of the yield curve only reflects expectations of future short-term rates. Yet, the yield curve generally slopes upward. The liquidity theory says that the yield curve incorporates expectations of short-term rates; however, the tendency for the yield curve to slope upward reflects the demand for a higher return to compensate investors for the extra interest rate risk associated with bonds with longer maturities.

(Module 25.5, LOS 25.h)

Question #27 of 79

Question ID: 1473374

If an active bond portfolio manager believes future spot rates will be lower than indicated by today's forward rates, then she will *most likely*:

- A) be indifferent because her holding period return will be unaffected.
- B) sell bonds because the market appears to be discounting future cash flows at "too high" of a discount rate.
- C) purchase bonds because the market is discounting future cash flows at "too high" of a discount rate.

Explanation

If an investor believes future spot rates will be lower than indicated by today's forward rates, then she should purchase bonds (at a presumably attractive price) because the market appears to be discounting future cash flows at "too high" of a discount rate.

(Module 25.2, LOS 25.c)

Question #28 of 79

Question ID: 1473395

If the liquidity preference hypothesis is true, what shape should the term structure curve have in a period where interest rates are expected to be constant?

- A) Downward sloping.
- B) Flat.
- C) Upward sloping.

Explanation

The liquidity theory holds that investors demand a premium to compensate them for interest rate exposure and the premium increases with maturity. Add this premium to a flat curve and the result is an upward sloping yield curve.

(Module 25.5, LOS 25.h)

Question #29 of 79

Question ID: 1473364

Suppose the government spot rate curve is flat at 3%. An active manager is planning on purchasing a five-year government bond at par. The realized return on this bond will *most likely* be:

- A) more than 3% if the bond is held to maturity while the yield curve remains flat but decreases below 3%. 
- B) 3% if the bond is held to maturity provided that the yield curve remains flat at 3%. 
- C) 3% if the bond is held to maturity regardless of the shape of the yield curve. 

Explanation

There is no price risk for a default-free bond held to maturity. However, there is reinvestment risk for the coupon payments received during the life of the bond (in this instance, the bond is a par bond and hence has the same coupon rate as its yield). If the yield curve shifts down, the reinvestment rate would be lower and the realized holding period return would be lower than 3%.

(Module 25.1, LOS 25.a)

Question #30 of 79

Question ID: 1473363

If the spot curve is upward sloping, the forward curve is *most likely* to be:

- A) steeper than the spot curve and above the spot curve. 
- B) parallel to the spot curve and below the spot curve. 
- C) parallel to the spot curve and above the spot curve. 

Explanation

When the spot curve is upward sloping, the forward curve will lie above the spot curve and will also be upward sloping with a steeper slope.

(Module 25.1, LOS 25.a)

Question #31 of 79

Question ID: 1473397

According to the pure expectations theory, which of the following statements is *most* accurate? Forward rates:

- A) are biased estimates of market expectations. 
- B) always overestimate future spot rates. 
- C) exclusively represent expected future spot rates. 

Explanation

The pure expectations theory, also referred to as the *unbiased* expectations theory, purports that forward rates are *solely a function of expected future spot rates*. Under the pure expectations theory, a yield curve that is upward (downward) sloping, means that short-term rates are expected to rise (fall). A flat yield curve implies that the market expects short-term rates to remain constant.

(Module 25.5, LOS 25.h)

Question #32 of 79

Question ID: 1473369

The following are some of the current par rates:

Year	Par rate
1	1.00%
2	2.00%
3	3.00%
4	4.00%
5	5.00%

Using bootstrapping, the 2-year spot rate is *closest* to:

A) 1.50%

B) 2.01%

C) 2.25%

Explanation

$S_1 = 1.00\%$ given

For a 2-year bond,

$$100 = \frac{2.00}{(1.01)} + \frac{102}{(1+S_2)^2}$$

$$98.01 = \frac{102}{(1+S_2)^2}$$

$$(1+S_2)^2 = 102/98.01 = 1.0407$$

$$(1+S_2) = 1.0201$$

$$S_2 = 2.01\%$$

(Module 25.1, LOS 25.b)

Question #33 of 79

Question ID: 1473396

Which of the following *most accurately* explains the "locked-in-rate" interpretation of forward rates? The forward rate allows an investor to lock in:

- A) a coupon rate for some future period. 
- B) a coupon rate for the current period. 
- C) an interest rate for some future period. 

Explanation

The pure expectations theory can be explained using a "locked-in-rate" line of reasoning, whereby forward rates are interpreted as the rate that can be "locked in" for some future period.

(Module 25.5, LOS 25.h)

Question #34 of 79

Question ID: 1473407

A portfolio manager who believed in the liquidity premium theory would expect:

- A) long-term securities to offer higher returns than short-term securities. 
- B) short-term rates to be lower than investors' expectations of short-term rates, because of the liquidity premium. 
- C) long-term rates to be higher than investors' expectations of future rates, because of the liquidity premium. 

Explanation

The liquidity theory of the term structure proposes that forward rates reflect investors' expectations of future rates plus a liquidity premium to compensate them for exposure to interest rate risk, and this liquidity premium is positively related to maturity. The implication of the liquidity theory is that forward rates, since they include a liquidity premium, are a biased estimate of the market's expectation of future spot rates.

(Module 25.5, LOS 25.h)

Question #35 of 79

Question ID: 1473394

Assuming the pure expectations theory is correct, an upward sloping yield curve implies:

- A) longer-term bonds are riskier than short-term bonds. 
- B) interest rates are expected to decline in the future. 
- C) interest rates are expected to increase in the future. 

Explanation

The yield curve slopes upward because short-term rates are lower than long-term rates. Since market rates are determined by supply and demand, it follows that investors (demand side) expect rates to be higher in the future than in the near-term.

(Module 25.5, LOS 25.h)

Question #36 of 79

Question ID: 1586231

Prices of zero-coupon, \$1 par bonds is shown below:

Maturity (years)	Price
1	\$0.9615
2	\$0.9070
3	\$0.8396
4	\$0.7629

The default risk of these bonds is similar to the default risk of surveyed banks based on which the swap rate is determined.

Government yield curve is given below:

Maturity (years)	Rate
1	3.05%
2	4.10%
3	5.25%
4	6.45%

The three-year swap spread is closest to:

A) 67 bps.

B) 78 bps.

C) 110 bps.

Explanation

The 3-year swap fixed rate SFR₃ is determined by solving:

$$\text{SFR}_3 (P_1 + P_2 + P_3) + P_3 = 1 \text{ or } \text{SFR}_3 (0.9615 + 0.9070 + 0.8396) + 0.8396 = 1$$

$$\text{SFR}_3 (2.7081) = 0.1604$$

$$\text{SFR}_3 = 0.1604/2.7081 = 5.92\%$$

$$\text{Swap spread} = \text{SFR}_3 - \text{3-year government bond yield} = 5.92\% - 5.25\% = 0.67\% \text{ or } 67 \text{ bps}$$

(Module 25.4, LOS 25.f)

Lihua Zhou has recently been hired by Ragun Asset Management, and is currently working for the fixed income team. Zhou receives a communication from Cindy Roll, chief economist, and makes the following notes:

Forecast 1: U.S. Federal Reserve is increasingly concerned with rising inflation and expected to tighten monetary policy during the next meeting.

Forecast 2: The EU zone is expected to see a bullish flattening of the yield curve.

Zhou notices that the firm's portfolio in the EU zone is almost exclusively medium remaining maturity (10-11 years) notes.

Zhou attends an informal discussion group with colleagues who have also recently joined the firm. During their discussion, Amanda Eden, one of Ragun's risk analysts, made two comments:

Comment 1: "There are lots of bond spreads, each with different bases. For instance, the spread I'm tracking at the moment measures the difference between the return on Treasury bills and the interest rate used to price the Eurodollar futures contracts."

Comment 2: "If the spread widens, it's an indicator that risk in the banking system is increasing."

Question #37 - 40 of 79

Question ID: 1473431

Based on Forecast 1, what is the *most* appropriate expected change in the shape of the yield curve?

- A) A bullish steepening. 
- B) A bearish steepening. 
- C) A bearish flattening. 

Explanation

To combat rising inflation, central banks may raise short-term rates (tightening monetary policy) resulting in a bearish flattening (increase in short-term rates) of the yield curve.

(Module 25.6, LOS 25.k)

Question #38 - 40 of 79

Question ID: 1473432

What would be the *most* appropriate duration-neutral strategy based on information presented in Forecast 2?

- A) Rotate into a barbell strategy. 
- B) Rotate into a long-maturity bullet portfolio. 
- C) Rotate into a short-maturity bullet portfolio. 

Explanation

A bullish flattening of the yield curve would result from decline in longer-term yields. Current portfolio composition is described as intermediate-term bullet portfolio. A rotation into a barbell strategy (short- and long-term) would allow price gains on longer maturity portion of the barbell, while keeping the change duration neutral. A shift to longer-term bullet would be most advantageous but would increase the duration of the portfolio (not duration-neutral). A shift to short bullet portfolio would not capitalize the expectations in Forecast 2.

(Module 25.6, LOS 25.k)

Question #39 - 40 of 79

Question ID: 1473433

Based on her first comment about bond spreads, Eden is *most* likely tracking which spread?

- A) TED spread. 
- B) MRR-OIS spread. 
- C) Z-spread. 

Explanation

TED spread is the difference between the MRR (captures the risk of interbank loans) and T-bill yield. The MRR-OIS spread measures the difference between MRR and the overnight indexed swap rate, and is a measure of general credit risk and well-being in the banking system.

The Z-spread is the constant spread, when added to benchmark spot rates, makes the present value of a bond's future cash flows equal to its market value. The Z-spread measures credit, liquidity, and option risk on a risky bond.

(Module 25.4, LOS 25.g)

Question #40 - 40 of 79

Question ID: 1473434

Eden's second comment about bond spreads is *most* likely:

- A) correct. 
- B) incorrect, because a narrowing spread indicates a reduction in risk in the banking system. 
- C) incorrect, because the spread does not give a specific indication about risk in the banking system. 

Explanation

A widening TED spread is an indicator that interbank loans are becoming more risky, and that market participants believe banks are becoming more likely to default.

(Module 25.4, LOS 25.g)

Question #41 of 79

Question ID: 1508670

During the recent credit crises in the country of Maltovia, several money market funds reported large losses. Subsequently, the Maltovian regulatory body imposed strict restrictions on maturity of securities that money market funds could invest in. The reaction of Maltovian regulatory body was *most likely* based on a belief in:

- A) market segmentation theory. 
- B) preferred habitat theory. 
- C) local expectations theory. 

Explanation

Money market funds generally invest in short-term securities. Their inclination to chase higher yields in the longer maturity spectrum is consistent with the preferred habitat theory whereby investors will leave their preferred habitat if they are compensated with higher returns. If Market segmentation theory held, investors would not have left their market segment and therefore no regulatory action would be necessary.

(Module 25.5, LOS 25.h)

Question #42 of 79

Question ID: 1473365

Use the following spot rate curve to answer this question:

Maturity	1	2	3
Spot rates	5%	5.5%	6%

The 1-year forward rate in one year [$f(1,1)$] and the 1-year forward rate in two years [$f(2,1)$] is *closest* to:

- | | $f(1,1)$ | $f(2,1)$ | |
|----|----------|----------|---|
| A) | 6% | 7% | ✓ |
| B) | 5.25% | 5.75% | ✗ |
| C) | 4% | 4.89% | ✗ |

Explanation

$$f(1,1) = (1+S_2)^2 / (1+S_1) - 1 = 6\%$$

$$f(2,1) = (1+S_3)^3 / (1+S_2)^2 - 1 = 7\%$$

(Module 25.1, LOS 25.a)

Question #43 of 79

Question ID: 1473381

Compared to a yield curve based on government bonds, swap rate curves are:

- | | | |
|----|---|---|
| A) | more comparable across countries and have a greater number of yields at various maturities. | ✓ |
| B) | more comparable across countries and have a smaller number of yields at various maturities. | ✗ |
| C) | less comparable across countries and have a greater number of yields at various maturities. | ✗ |

Explanation

Swap rate curves are typically determined by dollar denominated borrowing based on MRR. These rates are determined by market participants and are not regulated by governments. Swap rate curves are not affected by technical market factors that affect the yields on government bonds. Swap rate curves are also not subject to sovereign credit risk (potential government default on debt) that is unique to government debt in each country. Thus swap rate curves are more comparable across countries because they reflect similar levels of credit risk. There is also a wider variety of maturities available for swap rate curves, relative to a yield curve based on US Treasury securities, which has only four on-the-run maturities of two years or more. Swap rate curves typically have 11 quotes for maturities between 2 and 30 years.

(Module 25.3, LOS 25.e)

Question #44 of 79

Question ID: 1473375

The active bond portfolio management strategy of rolling down the yield curve is *most consistent* with:

- A) liquidity preference theory.
- B) segmented markets theory.
- C) pure expectations theory.

Explanation

Under the liquidity preference theory, investors would earn an extra return for investing in longer-maturity bonds rather than in shorter-maturity bonds. Such extra positive risk-premium linked to maturity of the bonds is absent in the pure expectations and the market segmentation theory.

(Module 25.2, LOS 25.d)

Question #45 of 79

Question ID: 1473370

The following are some of the current par rates:

Year	Par rate
1	5.00%
2	6.00%
3	7.00%

Using bootstrapping, the 3-year spot rate is *closest* to:

- A) 6.93%
- B) 6.67%
- C) 7.09%

Explanation

$S_1 = 5.00\%$ given

For the 2-year par bond,

$$100 = \frac{6.00}{(1.05)} + \frac{106}{(1+S_2)^2}$$

$$94.29 = \frac{106}{(1+S_2)^2}$$

$$(1+S_2)^2 = 106/94.29 = 1.1242$$

$$(1+S_2) = 1.0603$$

$$S_2 = 6.03\%$$

For the 3-year par bond,

$$100 = \frac{7.00}{(1.05)} + \frac{7.00}{(1.0603)^2} + \frac{107.00}{(1+S_3)^3}$$

$$87.11 = \frac{107.00}{(1+S_3)^3}$$

$$(1+S_3)^3 = 107/87.11 = 1.2283$$

$$(1+S_3) = 1.0709 \text{ or } S_3 = 7.09\%$$

(Module 25.1, LOS 25.b)

Question #46 of 79

Question ID: 1473366

The price of a five-year zero coupon bond is \$0.7835 for \$1 par and the price of a two-year zero-coupon bond is \$0.9426 for \$1 par. The three-year forward rate two years from now is *closest* to:

A) 4.87%

B) 6.36%

C) 5.54%

Explanation

$$F_{(2,3)} = P_5/P_2 = 0.7835/0.9426 = 0.8312$$

$$[1+f(2,3)]^3 = 1/F_{(2,3)} = 1/0.8312 = 1.2031$$

$$f(2,3) = 6.36\%$$

(Module 25.1, LOS 25.a)

Question #47 of 79

Question ID: 1473383

Government spot rate curve is given below:

Maturity (years)	Rate
1	3.05%
2	4.10%
3	5.25%
4	6.45%

The swap fixed rate for a period of 2 years is *closest* to:

A) 4.08%

B) 4.75%

C) 4.98%

Explanation

SFR₂ can be computed as:

$$\text{SFR}_2 / (1+S_1) + \text{SFR}_2 / (1+S_2)^2 + 1 / (1+S_2)^2 = 1$$

$$\text{SFR}_2 / (1.0305) + \text{SFR}_2 / (1.041)^2 + 1 / (1.041)^2 = 1$$

$$\text{SFR}_2 / (1.0305) + \text{SFR}_2 / (1.0837) + 1 / (1.0837) = 1$$

$$\text{SFR}_2 / (1.0305) + \text{SFR}_2 / (1.0837) = 0.07722$$

$$\text{SFR}_2 (1/(1.0305) + 1 / (1.0837)) = 0.07722$$

$$\text{SFR}_2 (1.8932) = 0.07722$$

$$\text{SFR}_2 = 0.07722/1.8932 = 0.0408 \text{ or } 4.08\%$$

(Module 25.4, LOS 25.f)

Holly Jameson, CFA, has recently started a new role as a bond analyst at her employer, Holt Investment Management, LLC, based in Farland. Her team leader has provided her with up-to-date but incomplete data on the benchmark term structure of interest rates, shown in Exhibit 1.

Exhibit 1: Farland Treasury Bond Rates

Maturity (years)	Spot	Forward	Par
1	2.30%	-	2.30%
2			3.14%
3			4.35%

Holly is evaluating a three-year, 6% annual coupon, benchmark bond trading at \$108.30.

In a discussion in the staff dining room shortly after she joined the firm, Holly's colleague, Doug Ross, made a confident assertion:

"I really don't know how some people find bond trading difficult. For each specific maturity, spot rates are always lower than forward rates, and forward rates are always lower than corresponding yield-to-maturity. So you can always achieve a higher return investing in shorter maturity bonds by rolling down the yield curve. I've been doing that since my first day on the job."

Holt offers both domestic and international bonds to its clients to enable them to benefit from risk reduction through diversification. She has carried out some preliminary research on the Happyland bond market and has found that the yield curve has an unexpected shape and does not seem to be driven by interest rate expectations. She asks her team leader, Al Smith, for advice, who tells her:

"Things are strange in Happyland. Rates are influenced simply by supply and demand of bonds of specific maturities. Different types of investors want particular maturity bonds, and they never seem to deviate from their preferences. High demand for five-year bonds has pushed prices up and yields down."

Alex Allan, a bond analyst colleague of Holly, started another discussion with the group by stating:

"I'm more interested in what happens to bond prices when the yield curve changes. I need to estimate how much prices will change when short-term yields increase while long-term yields stay constant."

Question #48 - 51 of 79

Question ID: 1473426

The benchmark bond being assessed by Holly is *most* likely:

- A) undervalued by \$3.69.
- B) overvalued by \$2.90.
- C) overvalued by \$3.75.

Explanation

There are two approaches to valuation of the bond.

Approach 1: Bootstrap the missing spot rates:

The two-year spot rate can be derived using the one-year spot rate (2.3%) and two-year par rate (3.14%) as follows:

$$100 = \frac{3.14}{1.023} + \frac{103.14}{(1+S_2)^2}$$

$$96.93 = \frac{103.14}{(1+S_2)^2}$$

$$(1+S_2)^2 = \frac{103.14}{96.93} = 1.06406$$

$$S_2 = 3.15\%$$

Likewise, the three-year spot rate can be calculated using the one-year spot rate (2.3%), the two-year spot rate derived above (3.15%), and the three-year par rate (4.35%):

$$100 = \frac{4.35}{1.023} + \frac{4.35}{(1.0315)^2} + \frac{104.35}{(1+S_3)^3}$$

$$91.66 = \frac{104.35}{(1+S_3)^3}$$

$$(1+S_3)^3 = \frac{104.35}{91.66} = 1.13845$$

$$S_3 = 4.42\%$$

Having derived the relevant spot rates, Holly can now value the three-year, 6% benchmark bond discounting the future cash flows using the spot rates:

$$P_0 = \frac{6}{1.023} + \frac{6}{(1.0315)^2} + \frac{106}{(1.0442)^3} = 104.58$$

Approach 2: Use the three-year par rate (4.35%) as the yield and use the standard TVM keys:

N=3; I/Y = 4.35%; PMT = 6; FV = 100; CPT PV = \$104.55

Note the difference in value is due to rounding error in calculating individual spot rates.

The bond is trading at \$108.30, and is therefore overvalued by \$3.75.

(Module 25.1, LOS 25.b)

Question #49 - 51 of 79

Question ID: 1473427

The comment made by Ross is *most* likely:

- A) inaccurate with respect to the statement about spot rates, forward rates, and yields. 
- B) inaccurate with respect to the statement about rolling down the yield curve. 
- C) inaccurate in both respects. 

Explanation

Ross's comments about the relative values of spots, forwards, and yields-to-maturity is inaccurate; when the yield curve is upward-sloping, forward curve will be higher than spot curve and spot curve will be higher than yield curve. If the yield curve is downward-sloping, the yield curve will be higher than the spot curve which will be higher than the forward curve.

Riding the yield curve describes a strategy whereby an investor will buy a bond with a maturity greater than his investment horizon and sell it before maturity. This strategy will provide higher returns than buying a bond and holding it to maturity over the same period *only if* the yield curve is upward sloping and its shape remains stable over the investment period. If the yield curve steepens sufficiently the strategy may produce losses.

(Module 25.2, LOS 25.d)

Question #50 - 51 of 79

Question ID: 1473428

Smith's comments about interest rates in Happyland *most* likely supports which theory of the term structure of interest rates?

- A) Liquidity preference theory.
- B) Segmented markets theory.
- C) Local expectations theory.

Explanation

The segmented markets theory states that the shape of the yield curve is determined by varying levels of supply and demand for bonds of specific maturities, and investors only deal in bonds with their preferred maturities, regardless of yields on bonds of different maturity.

The preferred habitat theory has similar principles, but investors may be tempted to invest in bonds that are not of their preferred maturity if expected returns are attractive enough, with low prices and high yields.

(Module 25.5, LOS 25.h)

Question #51 - 51 of 79

Question ID: 1473429

The *most* appropriate measure for Alex Allan to assess bond price sensitivity is:

- A) key rate duration.
- B) effective duration.
- C) Macaulay duration.

Explanation

Assuming an upward-sloping yield curve as a starting point, if short-term yields increase, but long-term yields remain constant, the yield curve will flatten. This is a non-parallel shift in the yield curve, which makes effective duration an inappropriate measure of bond price sensitivity. Key rate duration is the preferred measure for non-parallel shifts in the yield curve.

Effective duration is only suitable for measuring the sensitivity of a bond's price to parallel shifts in the yield curve. Macaulay duration measures the weighted average length of time to receive the present value of a bond's cash flows and is inappropriate in this instance.

(Module 25.6, LOS 25.i)

Question #52 of 79

Question ID: 1473409

With respect to local expectations theory, which of the following statements is *most consistent* with market evidence?

- A) Short-term holding period return of long-maturity bonds exceeds the short-term holding period returns of short-maturity bonds. 
- B) Short-term holding period return of short-maturity bonds exceeds the short-term holding period returns of long-maturity bonds. 
- C) Short-term holding period return of long-maturity bonds and the short-term holding period return of short-maturity bonds is the same. 

Explanation

Market evidence shows that short-term holding period returns from investing in long-maturity bonds exceed the short-term holding period returns from investing in short-maturity bonds.

(Module 25.5, LOS 25.h)

Question #53 of 79

Question ID: 1473414

What adjustment must be made to the key rate durations to measure the risk of a steepening of an already upward sloping yield curve?

- A) Increase the key rates at the short end of the yield curve. 
- B) Increase all key rates by the same amount. 
- C) Decrease the key rates at the short end of the yield curve. 

Explanation

Decreasing the key rates at the short end of the yield curve makes an upward sloping yield curve steeper. Performing the corresponding change in portfolio value will determine the risk of a steepening yield curve.

(Module 25.6, LOS 25.i)

Question #54 of 79

Question ID: 1473406

Assume that the interest rates in the future are not expected to differ from current spot rates. In such a case, the liquidity premium theory of the term structure of interest rates projects that the shape of the yield curve will be:

- A) variable.
- B) upward sloping.
- C) downward sloping.

**Explanation**

The liquidity theory holds that investors demand a premium to compensate them to interest rate exposure and the premium increases with maturity. When the yield curve under pure expectations is flat (i.e., interest rates in future are expected to be same as current rates), addition of liquidity premium (which increases with maturity) would result in an upward sloping yield curve.

(Module 25.5, LOS 25.h)

Question #55 of 79

Question ID: 1473421

Which of the following statements are *most accurate*?

- A) Short-term rates are typically more volatile than long-term rates.
- B) Volatility of short-term and long-term rates is typically equal.
- C) Long-term rates are typically more volatile than short-term rates.

**Explanation**

Volatility of rates is inversely related to maturity: long-term rates are less volatile than short-term rates.

(Module 25.6, LOS 25.j)

Question #56 of 79

Question ID: 1473405

Which of the following *most* accurately explains the "break-even-rate" interpretation of forward rates? The forward rate is the rate that will make an investor indifferent between investing:

- A) investing at the spot or forward interest rate.
- B) now or at a forward time.
- C) for the full investment horizon, or for part of it, and then rolling over the proceeds for the balance of the investment horizon at the forward rate.

**Explanation**

The pure expectations theory can be explained using a "break-even rate" line of reasoning. The break-even rate is the forward rate that leaves investors indifferent between investing for the full term of their investment horizon or investing in part of the horizon and rolling the investment over at the "break-even" forward rate for the remainder of the term.

(Module 25.5, LOS 25.h)

Question #57 of 79

Question ID: 1473367

Use the following spot rate curve to answer this question:

Maturity	1	2	3
Spot rates	5%	5.5%	6%

The price of a 1-year \$1 par, zero-coupon bond to be issued in two years is *closest* to:

A) \$0.9434

B) \$0.9345

C) \$0.8396

Explanation

$$f(2,1) = (1+S_3)^3 / (1+S_2)^2 - 1 = 7.01\%$$

$$F_{(2,1)} = 1 / [1 + f(2,1)] = 1 / (1.0701) = \$0.9345$$

(Module 25.1, LOS 25.a)

Question #58 of 79

Question ID: 1473361

Given annual spot interest rates for 1 year, 2 years, 3 years, 4 years, and 5 years, the maximum number of forward rates that can be derived is *closest* to:

A) 5

B) 8

C) 10

Explanation

Select all forward rates $f(j,k)$ such that $j+k \leq 5$. There are 10 forward rates possible: $f(1,1)$, $f(1,2)$, $f(1,3)$, $f(1,4)$, $f(2,1)$, $f(2,2)$, $f(2,3)$, $f(3,1)$, $f(3,2)$, $f(4,1)$

(Module 25.1, LOS 25.a)

Question #59 of 79

Question ID: 1473420

Volatility in short-term rates is *most likely* related to uncertainty about:

A) monetary policy.

B) the real economy.

C) inflation.

Explanation

Volatility in short-term rates is most likely linked to monetary policy, whereas volatility in long-term rates is most likely linked to uncertainty about the real economy and inflation.

(Module 25.6, LOS 25.j)

Martha Garret, CFA, manages fixed-income portfolios for Jones Brothers, Inc. (JBI). JBI has been in the portfolio management business for over 23 years and provides investors with access to actively managed equity and fixed-income portfolios. All of JBI's fixed-income portfolios are constructed using U.S. debt instruments. Garret's primary portfolio responsibilities are the Quasar Fund and the Nova Fund, both of which are long fixed-income portfolios consisting of Treasury securities in all maturity ranges. The Quasar Fund holdings as of March 15 are provided in Exhibit 1. A comparison of key rate durations for the Quasar Fund and Nova Fund is provided in Exhibit 2.

Exhibit 1: Quasar Fund

Bond	Maturity (years)	Coupon	Yield	Par Value	Market Value	Duration
A	2	5.0%	5.0%	4,000,000	4,000,000	1.86
B	5	4.5%	6.0%	3,500,000	3,278,851	4.32
C	15	8.0%	7.0%	2,750,000	3,000,468	8.90
D	30	6.5%	4.0%	6,450,000	9,238,340	15.90

Exhibit 2: Key Rate Durations for Quasar Fund & Nova Fund

Fund	Maturity (years)			
	2	5	15	30
Quasar Fund	0.90	1.20	1.80	6.10
Nova Fund	0.40	2.50	3.40	1.10

Of particular importance to Garret and her colleagues is the degree of interest rate risk exposure unique to each portfolio under JBI's management. Driving the increased awareness of the portfolios' interest rate exposure is the double-digit growth in assets under management that JBI's fixed-income portfolios have experienced in the past five years. Interest in the company's fixed income portfolios continues to grow and as a result, all portfolio managers are required to attend weekly meetings to discuss key portfolio risk factors. At the last meeting, Miranda Walsh, a principal at JBI, made the following comments:

"The variance of daily interest rate changes has been trending higher over the past three months, leading us to believe that a period of high volatility is approaching in the next 12 to 18 months. However, the reliability is questionable because the volatility estimates were derived using an option pricing model, which assumes constant interest rates."

"Also, the Treasury spot rate curve currently has a similar shape to the yield curve on Treasury coupon securities, which according to the market segmentation theory of interest rate term structure, indicates a relatively high level of demand from investors for intermediate term securities."

Overzealous trading by investors unwilling to move into other maturity ranges may create mispricing and opportunities for arbitrage."

After the meeting, Walsh and JBI's other principals met to discuss a new international portfolio opportunity. At Walsh's suggestion, the principals selected Garret as the lead portfolio manager for the new fund, which will be titled the Atlantic Fund. One of the other portfolio managers, Greg Terry, CFA, suggested to Garret that she utilize the MRR swap curve as a benchmark for the Atlantic fund rather than using local government yield curves. Terry justifies his suggestion by claiming that "the lack of government regulation in the swap market makes swap rates and curves directly comparable between different countries despite fewer maturity points with which to construct the curve as compared to a government yield curve. Furthermore, credit risk in the swap curves of various countries is similar, thus avoiding the complications associated with different levels of sovereign risk embedded in government yield curves." Intrigued by the idea of using the swap curve, Garret has her assistant begin gathering a range of current and forward MRR rates.

Question #60 - 61 of 79

Question ID: 1473411

Evaluate Walsh's comments regarding the method used to estimate the expected increase in interest rate volatility and the term structure of interest rates.

- A) Walsh is correct with respect to both interest rate volatility and term structure. 
- B) Walsh is incorrect with respect to both interest rate volatility and term structure. 
- C) Walsh is correct only with respect to interest rate volatility. 

Explanation

Option pricing models assume a constant volatility of interest rates but not a constant level of interest rates. Walsh's first statement is incorrect. The market segmentation theory says that the term structure of interest rates is determined solely by the supply/demand for a given maturity sector. The statement is incorrect, however, because high demand from investors (who wish to lend money) would push interest rates lower, not higher, as observed in the term structure.

(Module 25.3, LOS 25.e)

Question #61 - 61 of 79

Question ID: 1473412

Which of the following *best* evaluates Terry's justification for using the swap curve as the benchmark for the Atlantic Fund? Terry's justification is:

- A) incorrect because there are different levels of credit risk in the swap curves of different countries. 
- B) incorrect because there are actually more maturity points to construct the swap curve. 
- C) correct. 

Explanation

Terry's justification is incorrect. There are actually more maturity points in the swap market from which a swap curve can be derived. The rest of Terry's statements are correct.

(Module 25.6, LOS 25.i)

Question #62 of 79

Question ID: 1473413

The *least* important factor explaining the changes in the shape of the yield curve is:

- A) Level
- B) Steepness
- C) Curvature

Explanation

Changes in the shape of yield curve is explained by (in order of importance): level, steepness and curvature.

(Module 25.6, LOS 25.i)

Question #63 of 79

Question ID: 1473391

When the yield curve is downward sloping, the TED spread is *most likely* to be:

- A) zero.
- B) positive.
- C) negative.

Explanation

TED spread is defined as MRR minus T-bill yield and is expected to be positive to reflect the higher credit risk implied in MRR relative to T-bills. This would hold true regardless of the slope of the yield curve.

(Module 25.4, LOS 25.g)

Question #64 of 79

Question ID: 1473379

Joe McBath makes the following two statements:

- Statement 1: The swap rate curve indicates credit spread over government bond yield.
- Statement 2: The swap rate curve indicates the premium for time value of money at different maturities.

Joseph is *most likely* correct with regard to:

- A) Both statements.

B) Statement 1 but not statement 2.

C) Statement 2 but not statement 1.

Explanation

Swap rates are not spreads and hence the swap rate curve does not indicate credit spread. The swap rate curve can be used instead of government bond yield curve to indicate premium for time value of money.

(Module 25.3, LOS 25.e)

Question #65 of 79

Question ID: 1473424

Investors may rotating money out of risky investments and into relatively safe investments during a financial crisis would *most likely* lead to which of the following?

A) Bullish flattening.

B) Bearish flattening.

C) Bearish steepening.

Explanation

During periods of market turmoil, a flight to safety may reduce long-term government bond yields resulting in a bullish flattening of the yield curve.

(Module 25.6, LOS 25.k)

Question #66 of 79

Question ID: 1473372

Jon Smithson is a bond trader at Zezen Bank. The spot rate curve is currently flat. Smithson expects that the curve will become upward sloping in the next year. Based on this expectation, the *least appropriate* active strategy for Smithson would be to:

A) increase the duration of the portfolio.

B) sell all the long-term bonds in the portfolio and reinvest the proceeds in shorter-maturity bonds.

C) reduce the duration of the portfolio.

Explanation

The question is asking for least appropriate strategy. Given an expectation of steepening of the yield curve, an active bond manager would reduce the duration of the portfolio.

(Module 25.2, LOS 25.c)

Question #67 of 79

Question ID: 1473371

An active bond portfolio manager would *most* appropriately buy bonds when expected spot rates are:

- A) less than current forward rates. 
- B) greater than current forward rates. 
- C) equal to current forward rates. 

Explanation

When expected spot rates are less than the forward rates priced by the market, bonds are undervalued (they are discounted at too high a rate) and hence should be purchased.

(Module 25.2, LOS 25.c)

Question #68 of 79

Question ID: 1473385

For an interest rate swap, the swap spread is the difference between the:

- A) average fixed rate and the average floating rate over the life of the contract. 
- B) fixed rate and the floating rate in a given period. 
- C) swap rate and the corresponding Treasury rate. 

Explanation

The swap spread is the swap rate minus the corresponding Treasury rate.

(Module 25.4, LOS 25.f)

Question #69 of 79

Question ID: 1473415

Which of the following *best* describes key rate duration? Key rate duration is determined by:

- A) shifting the whole yield curve in a parallel manner. 
- B) changing the yield of a specific maturity. 
- C) changing the curvature of the entire yield curve. 

Explanation

Key rate duration can be defined as the approximate percentage change in the value of a bond or bond portfolio in response to a 100 basis point change in a key rate, holding all other rates constant, where every security or portfolio has a set of key rate durations, one for each key rate maturity point.

(Module 25.6, LOS 25.i)

Question #70 of 79

Question ID: 1473402

According to the pure expectations theory, how are forward rates interpreted? Forward rates are:

- A) expected future spot rates. 
- B) equal to futures rates. 

C) expected future spot rates if the risk premium is equal to zero.

Explanation

The pure expectations theory, also referred to as the unbiased expectations theory, purports that forward rates are solely a function of expected future spot rates. This implies that long-term interest rates represent the geometric mean of future expected short-term rates, nothing more.

(Module 25.5, LOS 25.h)

Question #71 of 79

Question ID: 1473373

It is now January 1, 20x7. The one-year spot rate now is exactly equal to the one-year forward rate for a loan in one year as of January 1, 20x6. The current forward price of \$1 par, zero-coupon bond for delivery on January 1, 20x8 will *most likely* be:

A) lower than it was on January 1, 20x6.

B) the same as it was on January 1, 20x6.

C) higher than it was on January 1, 20x6.

Explanation

If the spot rates evolve exactly as indicated by the forward curve, the forward price would remain unchanged.

(Module 25.2, LOS 25.c)

Question #72 of 79

Question ID: 1473417

An analyst has a list of key rate durations for a portfolio of bonds. If only one interest rate on the yield curve changes, the effect on the value of the bond portfolio will be the change of that rate multiplied by the:

A) key rate duration associated with the maturity of the rate that changed.

B) weighted average of the key rate durations.

C) median of the key rate durations.

Explanation

This is how an analyst uses key rate durations: For a given change in the yield curve, each rate change is multiplied by the associated key rate duration. The sum of those products gives the change in the value of the portfolio. If only the five-year interest rate changes, for example, then the effect on the portfolio will be the product of that change times the five-year key rate duration.

(Module 25.6, LOS 25.i)

Question #73 of 79

Question ID: 1473376

Which one of the following actions is *most consistent* with the strategy of riding an upward sloping the yield curve? Buying bonds with a maturity:

- A) shorter than the investor's horizon.
- B) equal to the investor's horizon.
- C) longer than the investor's horizon.

Explanation

If the yield curve is upward sloping and is expected to remain the same, higher returns can be obtained by riding the yield curve, i.e., buying bonds with a longer maturity than the investor's horizon.

(Module 25.2, LOS 25.d)

Question #74 of 79

Question ID: 1473399

What are the implications for the shape of the yield curve according to the liquidity theory?
The yield curve:

- A) may have any shape.
- B) is always flat.
- C) must be upward sloping.

Explanation

The liquidity theory holds that investors demand a premium to compensate them to interest rate exposure and the premium increases with maturity. Even after adding the premium to a steep downward sloping yield curve the result will still be downward sloping.

(Module 25.5, LOS 25.h)

Question #75 of 79

Question ID: 1473388

Z-spread is *most accurately* described as the constant spread that is:

- added to the spot rate curve to generate discount rates for each of the bond's cash flows such that the present value of the cash flows is exactly equal to the market price of the bond.
- equal to the difference between a bond's yield and the yield on a government bond.
- added to the zero volatility binomial tree such that an option-free bond is correctly valued.

Explanation

Z-spread is the constant spread added to the spot rate curve to generate discount rates which then value the bond at its current market price. The difference between yields of a risky and government bond will be same as the Z-spread only when the yield curve is flat. A Zero-volatility binomial tree does not exist!

(Module 25.4, LOS 25.g)

Question #76 of 79

Question ID: 1473398

According to the liquidity theory, how are forward rates interpreted? Forward rates are:

- A) expected future spot rates. ✗
- B) expected future spot rate plus a rate exposure premium. ✓
- C) equal to futures rates. ✗

Explanation

The liquidity theory of the term structure proposes that forward rates reflect investors' expectations of future rates plus a liquidity premium to compensate them for exposure to interest rate risk, and this liquidity premium is positively related to maturity. The implication of the liquidity theory is that forward rates are a biased estimate of the market's expectation of future rates, since they include a liquidity premium.

(Module 25.5, LOS 25.h)

Question #77 of 79

Question ID: 1473390

A 2-year \$1,000 par, 5% (semi-annual pay) Mexa-corp bond has a Z-spread of 45bps. Using the following spot curve, compute the invoice price of the bond.

Maturity	0.50	1.00	1.50	2.00
Spot rates	4.50%	5%	5.25%	5.5%

- A) \$993.45 ✗
- B) \$982.65 ✓
- C) \$956.32 ✗

Explanation

Add the Z-spread to each of the spot rates to discount the bond's cash flows

$$\frac{25}{\left(1 + \frac{0.045 + 0.0045}{2}\right)} + \frac{25}{\left(1 + \frac{0.05 + 0.0045}{2}\right)^2} + \frac{25}{\left(1 + \frac{0.0525 + 0.0045}{2}\right)^3} + \frac{1025}{\left(1 + \frac{0.055 + 0.0045}{2}\right)^4} = \$982.$$

(Module 25.4, LOS 25.g)

Question #78 of 79

Question ID: 1473380

Which of the following is NOT a reason why market participants prefer the swap rate curve over a government bond yield curve? The swap market:

- A) reflects sovereign credit risk. ✓
- B) is free of government regulation. ✗
- C) it is not affected by technical factors. ✗

Explanation

Swap rate curves are typically determined by dollar denominated borrowing based on MRR. These rates are determined by market participants and are not regulated by governments. Swap rate curves are not affected by technical market factors that affect the yields on government bonds. The swap rate curve is also not subject to sovereign credit risk (potential government default on debt) that is unique to each country.

(Module 25.3, LOS 25.e)

Question #79 of 79

Question ID: 1473419

Volatility in long-term rates is *most likely* related to uncertainty about:

- A) the real economy and inflation.
- B) fiscal policy.
- C) central bank actions.

Explanation

Volatility in long-term rates is most likely linked to uncertainty about the real economy and inflation, whereas volatility in short-term rates is most likely linked to monetary policy.

(Module 25.6, LOS 25.j)
