

Question #1 of 98

Question ID: 1473535

Which of the following is equal to the value of a noncallable / nonputable convertible bond?

The value of the corresponding:

- A) callable bond plus the value of the call option on the stock.
 - B) straight bond.
 - C) straight bond plus the value of the call option on the stock.
-

Question #2 of 98

Question ID: 1473537

Which of the following statements is *most* accurate concerning a convertible bond? A

convertible bond's value depends:

- A) only on changes in the market price of the stock.
 - B) on both interest rate changes and changes in the market price of the stock.
 - C) only on interest rate changes.
-

Question #3 of 98

Question ID: 1473514

The effective convexity of a bond is most likely to be negative if the bond is:

- A) callable.
 - B) putable.
 - C) option-free.
-

Bill Woods, CFA, is a portfolio manager for Matrix Securities Fund, a closed-end bond fund that invests in U.S. Treasuries, mortgage-backed securities (MBS), asset-backed securities (ABS), and MBS derivatives. The fund has assets of approximately \$400 million, has a current stock price of \$14.50 and a net asset value (NAV) of \$16.00. Woods is a member of a four person investment team that is responsible for all aspects of managing the portfolio, including interest rate forecasting, performing basic financial analysis and valuation of the portfolio, and selecting appropriate investments for Matrix. His expertise is in the analysis and valuation of MBS and ABS.

The fund pays a \$0.12 monthly dividend that is paid from current income. The basic operating strategy of Matrix is to leverage its capital by investing in fixed income securities, and then financing those assets through repurchase agreements. Matrix then earns the spread between the net coupon of the underlying assets and the cost to finance the asset. Therefore, when evaluating a security for investment, it is critical that Matrix can be reasonably assured that it will earn a positive spread.

During the course of his analysis, Woods utilizes several methodologies to evaluate current portfolio holdings and potential investments. Valuation methods he uses include nominal spreads, Z-spreads, and option-adjusted spreads (OAS). There is ongoing debate among the investment team as to the merits and shortcomings of each of the methods. Woods believes that the OAS method is by far a superior tool in all circumstances, while his fellow portfolio manager, Yuri Ackerman, feels that each of the methods can at times serve a useful purpose. Wood and Ackerman's current discussion involves two similar FNMA adjustable-rate mortgage (ARM) securities Wood is considering purchasing. Both ARM "A" and ARM "B" are indexed off of 6-month LIBOR, are new production, and have similar net coupons.

Select Financial Information:

ARM	Net Coupon	WAM	Nominal Spread	OAS (bps)	Z-spread (bps)
A	6.27%	360	81	98	135
B	6.41%	358	95	116	129

Woods recommends that Matrix purchase ARM "A" with the 6.27% net coupon. He has based his conclusion on the calculated OAS of the securities, which he believes indicates that ARM "A" is the cheaper of the two securities. Ackerman disagrees with Woods, arguing that OAS

is only one component of any analysis, and that a buy or sell recommendation should not be made based upon the OAS spread alone. Ackerman claims that other measures, such as one of the many duration measures and convexity, need to be incorporated into the analysis. He points out that both ARMs have equal convexities, but ARM "A" has a duration of 7.2 years and ARM "B" has duration of 6.8 years. These characteristics will affect the expected return in any interest rate scenario. Woods admits that he had not considered the differences in the bond's durations, and he acknowledges that others factors should be considered before a recommendation can be made.

Question #4 - 7 of 98

Question ID: 1586258

Woods is *most likely* resistant to the zero-volatility spread because the spread:

- A) only considers one path of interest rates, the current Treasury spot rate curve.
- B) fails to consider price risk, which is uncertainty regarding terminal cash flows.
- C) does not indicate how much of the spread reflects the significant prepayment risk associated with MBS.

Question #5 - 7 of 98

Question ID: 1586259

In general, the investment team at Matrix attempts to buy "cheap" securities because they are undervalued on a relative basis. What is a characteristic of a "cheap" security for a given Z-spread and effective duration?

- A) High OAS relative to the required OAS and high option costs.
- B) High OAS relative to the required OAS and low option costs.
- C) Low OAS relative to the required OAS and low option costs.

Question #6 - 7 of 98

Question ID: 1586260

Which of the two bonds Woods is considering purchasing has the greater interest rate exposure?

- A) ARM B, because it has a smaller duration.
- B) The interest rate exposure cannot determine without a specific measure of convexity.
- C) ARM A, because it has a larger duration.

Question #7 - 7 of 98

Question ID: 1586261

Matrix also currently has investments in several ABS. Which of the following spread measures is *most appropriate* in the analysis of ABS backed by credit card receivables?

- A) Monte Carlo simulation model, because representative paths can be utilized.
- B) Z-spread, because credit card ABS have no prepayment option.
- C) OAS, because the cash flows are interest rate path dependent.

Alnoor Hudda, CFA, is valuing two floaters issued by Mateo Bank. Both floaters have a par value of \$100, three year life and pay based on annual MRR. Hudda has generated the following binomial tree for MRR.

1-year forward rates starting in year:

0	1	2
---	---	---

2%	5.7798%	6.0512%
	3.8743%	4.0562%
		2.7190%

Question #8 - 9 of 98

Question ID: 1473526

Value of a capped floater with a cap of 4% is closest to:

- A) \$96.71
- B) \$97.38
- C) \$98.70

Question #9 - 9 of 98

Question ID: 1473527

Value of the cap in a capped floater with a cap of 4% is closest to:

- A) \$4.41
- B) \$1.29
- C) \$1.23

Question #10 of 98

Question ID: 1473553

Suppose that the stock price of a common stock increases by 10%. Which of the following is *most* accurate for the price of the recently issued convertible bond? The value of the convertible bond will:

- A) increase by 10%.
- B) increase by less than 10%.
- C) remain unchanged.

Question #11 of 98

Question ID: 1473482

Using the following tree of semiannual interest rates what is the value of a 5% callable bond that has one year remaining to maturity, a call price of 99 and pays coupons semiannually?

	7.76%
6.20%	
	5.45%

- A) 97.17.
- B) 98.29.
- C) 99.01.

Kate Inka is a new hire for Maya Incorporated, a fixed income fund manager. On her first week on the job, she is asked to prepare a presentation on valuation and analysis of bonds with embedded options.

Inka starts her presentation with the following three statements:

Statement "In times of increased expectations of interest rate volatility the value of callable bonds will fall."

1:

Statement 2: "When trying to analyze the return for credit and liquidity risk on a corporate callable bond relative to a government bond, the Z-spread must be calculated. The Z-spread can be viewed as the constant spread added to treasury spot rates such that the present value of the callable bonds coupons and principal equate to its market price."

Statement 3: "When analyzing the interest rate risk of a callable bond it is worth keeping in mind that its effective convexity will be less than or equal to the equivalent option free bond."

Inka is analyzing a three-year, 6% annual coupon, \$100 par callable bond. The bond has a European call feature allowing it to be called at 101% of par in two years' time. Inka uses a binomial tree assuming interest rate volatility of 20% as shown in Exhibit 1.

Exhibit 1: Binomial Lattice

T_0	T_1	T_2
-------	-------	-------

6.34%

5.45%

3% ?????

3.65%

2.85%

Inka makes the following three comments about her binomial tree exercise:

Comment 1: "If the spot and expected future 1-period rates in the binomial tree have been derived from treasury securities we should be aware that the backwardly induced value of a corporate bond would be too high relative to its market price."

Comment 2: "For a corporate callable bond, the option adjusted spread must be added as a fixed margin to all the treasury spot and expected future 1-period rates so that the backwardly induced price converges with market price."

Comment 3: "If we were to increase our assumption of interest rate volatility used to create the binomial tree, the estimated option adjusted spread would be smaller."

Finally, Inka makes three comments on her use of effective duration:

Comment 1: "Given that a corporate callable bond will exhibit negative convexity when yields are low, care must be taken when interpreting effective duration, as essentially the computation averages the impact of the up and down shock on bond price. Perhaps the non-symmetrical price reaction to yield increases and decreases would be better captured by looking at one-sided durations."

Comment 2: "Effective duration is an incomplete measure of interest rate risk as it fails to adequately capture option risk. For example, callable bonds are more sensitive to interest rate risk due to embedded options and as such have a higher effective duration."

Comment 3: "One method of capturing shaping risk is to compute one-sided durations. A 20-year bond callable after 10 years with a low coupon is likely to have the highest one-sided duration corresponding to the call date. If the coupon is increased the one-sided duration corresponding to the call date declines but the maturity matched 20-year one-sided duration increases."

How many of Inka's opening statements are *correct*?

- A) Two.
 - B) Three.
 - C) One.
-

Question #13 - 15 of 98

Question ID: 1482447

Which value for the backwardly induced price of the corporate callable bond using the binomial tree in Exhibit 1 is *most* accurate?

- A) \$105.69.
 - B) \$104.89.
 - C) \$105.20.
-

Question #14 - 15 of 98

Question ID: 1482448

How many of Inka's comments about her binomial tree exercise are *correct*?

- A) One.
 - B) Two.
 - C) Three.
-

Question #15 - 15 of 98

Question ID: 1586268

How many of Inka's comments about duration are accurate?

- A) One.
 - B) Three.
 - C) Two.
-

Question #16 of 98

Question ID: 1473474

Which of the following is the appropriate "nodal decision" within the backward induction methodology of the interest tree framework for a puttable bond?

- A) Min(put value, discounted value).
 - B) Max(par value, discounted value).
 - C) Max(put price, discounted value).
-

Question #17 of 98

Question ID: 1473506

Joseph Dentice, CFA is evaluating three bonds. All three bonds have a coupon rate of 3%, maturity of five years and are generally identical in every respect except that bond A is an option-free bond, bond B is callable in two years and bond C is puttable in two years.

If interest rates decrease, the duration of which bond is *most likely* to decrease?

- A) Bond C.

B) Bond A.

C) Bond B.

Question #18 of 98

Question ID: 1473533

Which of the following *correctly* describes one of the basic features of a convertible bond? A convertible bond is a security that can be converted into:

A) common stock at the option of the investor.

B) common stock at the option of the issuer.

C) another bond at the option of the issuer.

Question #19 of 98

Question ID: 1473475

Which of the following is the appropriate "nodal decision" within the backward induction methodology of the interest tree framework for a callable bond?

A) $\text{Max}(\text{call price, discounted value})$.

B) $\text{Min}(\text{par value, discounted value})$.

C) $\text{Min}(\text{call price, discounted value})$.

Question #20 of 98

Question ID: 1508674

Which of the following statements about how interest rate volatility affects the value bond is *most* accurate? When interest rate volatility increases, the value of a:

A) callable bond decreases.

B) puttable bond decreases.

C) straight bond decreases.

Question #21 of 98

Question ID: 1508675

If a bond's key rate durations for maturity points shorter than the bond's maturity are negative, it is *most likely* that the bond being analyzed is a:

A) zero coupon bond.

B) puttable bond.

C) callable bond.

Eric Rome works in the back office at Finance Solutions, a limited liability firm that specializes in designing basic and sophisticated financial securities. Most of their clients are commercial and investment banks, and the detection, and control of interest rate risk is Financial Solution's competitive advantage.

One of their clients is looking to design a fairly straightforward security: a callable bond. The bond pays interest annually over a two-year life, has a 7% coupon payment, and has a par value of \$100. The bond is callable in one year at par (\$100).

Rome uses a binomial tree approach to value the callable bond. He's already determined, using a similar approach, that the value of the option-free counterpart is \$102.196. This price came from discounting cash flows at on-the-run rates for the issuer. Those discount rates are given below:

Rome is also interested in the 2027 6% convertible bond of Stellar Inc. The bond can be converted into 25 shares of common stock and is trading at \$1024. Stellar's current stock price is \$32. Comparable nonconvertible bonds currently yield 6%.

Question #22 - 25 of 98

Question ID: 1586243

Using the binomial tree model, what is the value of the callable bond?

- A) \$101.735.
 - B) \$95.521.
 - C) \$102.196.
-

Question #23 - 25 of 98

Question ID: 1586244

What is the value of the call option embedded in this bond?

- A) \$6.675.
 - B) \$0.461.
 - C) \$12.924.
-

Question #24 - 25 of 98

Question ID: 1586245

If the bond is puttable in one year at par, the value of the put is *closest* to:

- A) \$0.461.
 - B) \$0.291.
 - C) \$12.487.
-

Question #25 - 25 of 98

Question ID: 1586246

The market conversion premium ratio for Stellar's convertible bond is *closest* to:

- A) 20.6%.
 - B) 28%.
 - C) 2.40%
-

Question #26 of 98

Question ID: 1473554

Which of the following scenarios will lead to a convertible bond underperforming the underlying stock? The:

- A) stock price is stable.
 - B) stock price falls.
 - C) stock price rises.
-

Question #27 of 98

Question ID: 1473490

Bill Moxley, CFA is evaluating three bonds for inclusion in fixed income portfolio for one of his pension fund clients. All three bonds have a coupon rate of 3%, maturity of five years and are generally identical in every respect except that bond A is an option-free bond, bond B is callable in two years and bond C is puttable in two years. The yield curve is currently flat.

If the yield curve is expected to have a parallel downward shift, the bond with the highest price appreciation is *least likely* to be:

- A) Bond A
 - B) Bond B
 - C) Bond C
-

Question #28 of 98

Question ID: 1473536

For a convertible bond with a call provision, with respect to the bond's convertibility feature and the call feature, the Black-Scholes option model can apply to:

- A) only one feature.
 - B) both features.
 - C) neither features.
-

Question #29 of 98

Question ID: 1473468

How does the value of a callable bond compare to a noncallable bond? The callable bond value is:

- A) lower or higher.
 - B) lower.
 - C) higher.
-

Question #30 of 98

Question ID: 1473512

Joseph Dentice, CFA is evaluating three bonds. All three bonds have a coupon rate of 3%, maturity of five years and are generally identical in every respect except that bond A is an option-free bond, bond B is callable at any time at par and bond C is puttable at any time at par. Yield curve is currently flat at 3%.

The bond with the lowest one-sided down-duration is *most likely* to be:

- A) Bond B.
 - B) Bond A.
 - C) Bond C.
-

Question #31 of 98

Question ID: 1473541

A convertible bond has a conversion ratio of 12 and a straight value of \$1,010. The market value of the bond is \$1,055, and the market value of the stock is \$75. What is the market conversion price and premium over straight value of the bond?

<u>Market conversion price</u>	<u>Premium over straight value</u>
A) \$75.00	0.1029
B) \$87.92	0.0446
C) \$84.17	0.1222

Question #32 of 98

Question ID: 1473491

Generally speaking, an analyst would like the option adjusted spread (OAS) to be large, controlling for:

- A) Credit and liquidity risk.
 - B) Credit, liquidity and option risk.
 - C) Option risk.
-

Question #33 of 98

Question ID: 1473470

How is the value of the embedded call option of a callable bond determined? The value of the embedded call option is:

- A) determined using the standard Black-Scholes model.
 - B) equal to the amount by which the callable bond value exceeds the option-free bond value.
 - C) the difference between the value of the option-free bond and the callable bond.
-

Question #34 of 98

Question ID: 1473471

A callable bond and an option-free bond have the same coupon, maturity and rating. The callable bond currently trades at par value. Which of the following lists *correctly* orders the values of the indicated items from lowest to highest?

- A) \$0, embedded call, callable bond, option-free bond.
 - B) Embedded call, callable bond, \$0, option-free bond.
 - C) Embedded call, \$0, callable bond, option-free bond.
-

Question #35 of 98

Question ID: 1473465

The value of a callable bond is equal to the:

- A) callable bond plus the value of the embedded call option.
- B) option-free bond value minus the value of the call option.
- C) callable bond value minus the value of the put option minus the value of the call option.

Question #36 of 98

Question ID: 1473550

The value of a convertible bond is most likely to be calculated as the value of an equivalent straight bond:

- A) plus the value of a call option on the bond.
 - B) plus the value of a call option on the stock.
 - C) minus the value of a put option on the bond.
-

Question #37 of 98

Question ID: 1473510

Which bonds would have its maturity-matched rate as its most critical rate?

- A) High coupon callable bonds.
 - B) Low coupon puttable bonds.
 - C) Low coupon callable bonds.
-

Question #38 of 98

Question ID: 1473511

For an option-free bond trading at par, it is *least likely* that:

- A) The spot rate for the maturity of the bond is least important rate affecting the value of the bond.
 - B) The rate durations for all the rates other than the maturity-matched rate are zero.
 - C) Its maturity key rate duration is the same as its effective duration.
-

Question #39 of 98

Question ID: 1473539

Suppose the market price of a convertible security is \$1,050 and the conversion ratio is 26.64. What is the market conversion price?

- A) \$1,050.00.
 - B) \$26.64.
 - C) \$39.41.
-

Question #40 of 98

Question ID: 1473538

For a convertible bond without any other options, the call feature implied by the convertibility feature will do all of the following EXCEPT:

- A) increase the value of the bond over that of a comparable option-free bond.
 - B) cause negative convexity.
 - C) place a lower limit on the possible values of the bond.
-

George Nagy is a fixed income manager with Luna Securities. Nagy is analyzing several securities issued by Redna, Inc. First, he is looking at a three-year, annual-pay floating rate note with an embedded cap of 6.5% paying coupons in arrears.

Nagy's assistant has provided him with the binomial interest rate tree below (computed with assumed volatility of 25%) to aid in her analysis.

T_0	T_1	T_2
	9.892%	
	7.704%	
6%	6%	
	4.673%	
	3.639%	

A three-year, Redna, Inc., callable bond is currently trading at a price of \$102. An otherwise identical straight bond is also trading.

Nagy obtains the report of the firm's chief economist indicating that rates are trending lower.

Question #41 - 44 of 98

Question ID: 1473529

What is the value of the capped floater using Nagy's line manager's binomial tree of interest rate expectations?

- A) \$98.80.
- B) \$99.26.
- C) \$101.44.

Question #42 - 44 of 98

Question ID: 1473530

Which of the following statements is/are correct?

Statement I: The straight bond should trade for less than \$102.

Statement II: If interest rate volatility were to increase then the price differential between the two Redna bonds would widen.

- A) Both statements are correct.
- B) Statement I is correct but Statement II is incorrect.
- C) Statement I is incorrect but Statement II is correct.

Question #43 - 44 of 98

Question ID: 1473531

Suppose Redna were to issue a bond that was identical in all respects to the existing callable bond except that instead it was puttable. How would a binomial tree valuation be adapted?

- A) The put option becomes an effective floor price at each applicable node, instead of the call's effective ceiling price.
- B) The put option becomes an effective floor price at each applicable node, as well as the call's effective ceiling price.
- C) The put option becomes an effective ceiling price at each applicable node.

Question #44 - 44 of 98

Question ID: 1473532

Using the report of the economist, which of the following order of effective durations (highest to lowest) of otherwise identical bonds is *most* accurate:

- A) callable, putable, straight.
 - B) straight, callable, putable.
 - C) straight, putable, callable.
-

Question #45 of 98

Question ID: 1473473

A callable bond and an option-free bond have the same coupon, maturity and rating. The callable bond currently trades at par value. Which of the following lists *correctly* orders the values of the indicated items from lowest to highest?

- A) Embedded call, \$0, callable bond, option-free bond.
 - B) Embedded call, callable bond, \$0, option-free bond.
 - C) \$0, embedded call, callable bond, option-free bond.
-

Question #46 of 98

Question ID: 1473503

Which of the following *most accurately* explains how the effective convexity is computed using the binomial model. In order to compute the effective convexity the:

- A) binomial tree has to be shifted upward and downward by the same amount for all nodes.
 - B) yield curve has to be shifted upward and downward in a parallel manner and the binomial tree recalculated each time.
 - C) volatility has to be shifted upward and downward and the binomial tree recalculated each time.
-

Question #47 of 98

Question ID: 1473507

Joseph Dentice, CFA is evaluating three bonds. All three bonds have a coupon rate of 3%, maturity of five years and are generally identical in every respect except that bond A is an option-free bond, bond B is callable in two years and bond C is putable in two years.

The bond with the lowest duration is *least likely* to be:

- A) Bond A.
 - B) Bond B.
 - C) Bond C.
-

Question #48 of 98

Question ID: 1473479

Using the following tree of semiannual interest rates what is the value of a putable semiannual bond that has one year remaining to maturity, a put price of 98 and a 4% coupon rate? The bond is putable today.

	7.59%
6.35%	
	5.33%

- A) 98.00.
- B) 98.75.
- C) 97.92.

Question #49 of 98

Question ID: 1473501

Sharon Rogner, CFA is evaluating three bonds for inclusion in fixed income portfolio for one of her pension fund clients. All three bonds have a coupon rate of 3%, maturity of five years and are generally identical in every respect except that bond A is an option-free bond, bond B is callable in two years and bond C is putable in two years. Rogner computes the OAS of bond A to be 50bps using a binomial tree with an assumed interest rate volatility of 15%.

If Rogner revises her estimate of interest rate volatility to 10%, the computed OAS of Bond C would *most likely* be:

- A) equal to 50bps.
- B) higher than 50bps.
- C) lower than 50bps.

MediSoft Inc. develops and distributes high-tech medical software used in hospitals and clinics across the United States and Canada. The firm's software provides an integrated solution to monitoring, analyzing, and managing output from a variety of diagnostic medical equipment including MRIs, CT scans, and EKG machines. MediSoft has grown rapidly since its inception ten years ago, averaging 25% growth in sales over the past decade. The company went public three years ago. Twelve months after its IPO, MediSoft made two semiannual coupon bond offerings, the first of which was a convertible bond. At the time of issuance, the convertible bond had a coupon rate of 7.25%, a par value of \$1,000, a conversion price of \$55.56, and ten years until maturity. Two years after issuance, the bond became callable at 102% of par value. Soon after the issuance of the convertible bond, the company issued another series of bonds, which were putable but contained no conversion or call features. The putable bonds were issued with a coupon of 8.0%, a par value of \$1,000, and 15 years until maturity. One year after their issuance, the put feature of the putable bonds became active, allowing the bonds to be put at a price of 95% of par value, and increasing linearly over five years to 100% of par value. MediSoft's convertible bonds are now trading in the market for a price of \$947 with an estimated straight value of \$917. The company's putable bonds are trading at a price of \$1,052. Volatility in the price of MediSoft's common stock has been relatively high over the past few months. Currently, the stock is priced at \$50 on the New York Stock Exchange and is expected to continue its annual dividend in the amount of \$1.80 per share.

High-tech industry analysts for Brown & Associates, a money management firm specializing in fixed-income investments, have been closely following MediSoft ever since it went public three years ago. In general, portfolio managers at Brown & Associates do not participate in initial offerings of debt investments, preferring instead to see how the issue trades before considering taking a position in the issue. Because MediSoft's bonds have had ample time to trade in the marketplace, analysts and portfolio managers have taken an interest in the company's bonds. At a meeting to discuss the merits of MediSoft's bonds, the following comments were made by various portfolio managers and analysts at Brown & Associates:

"Choosing to invest in MediSoft's convertible bond would benefit our portfolios in many ways, but the primary benefit is the limited downside risk associated with the bond. Because the straight value will provide a floor for the value of the convertible bond, downside risk is limited to the difference between the market price of the bond and the straight value."

"Decreasing volatility in the price of MediSoft's common stock as well as increasing volatility in the level of interest rates are expected in the near future. The combined effects of these changes in volatility will be a decrease in the price of MediSoft's putable bonds and an increase in the price of the convertible bonds. Therefore, only the convertible bonds would be a suitable purchase."

Question #50 - 52 of 98

Question ID: 1473543

Assuming the common stock of MediSoft underwent a one-for-two reverse split, how would the features of the company's bonds be adjusted? The:

- A) conversion value of the convertible bond would be reduced by half.
 - B) market conversion price of the convertible bond would be reduced by half.
 - C) conversion ratio of the convertible bond would be reduced by 50%.
-

Question #51 - 52 of 98

Question ID: 1473544

Under what circumstances will the analyst's comments regarding the limited downside risk of MediSoft's convertible bonds be accurate?

- A) The convertible bond is trading in the market as a common stock equivalent.
 - B) Short-term and long-term interest rates are expected to remain the same.
 - C) The Federal Reserve Bank decides to pursue a restrictive monetary policy.
-

Question #52 - 52 of 98

Question ID: 1473545

Subsequent to purchasing one of the putable bonds for his portfolio, one of the managers at Brown & Associates realized that the bond contained a soft put. Which of the following securities cannot be used to redeem the bond in the event the bond becomes putable?

- A) Thirty-year Treasury notes with a coupon of 4.5%.
 - B) MediSoft's 9.0% subordinated notes with a maturity of 10 years.
 - C) Shares of MediSoft's common stock.
-

Question #53 of 98

Question ID: 1473488

Bill Moxley, CFA is evaluating three bonds for inclusion in fixed income portfolio for one of his pension fund clients. All three bonds have a coupon rate of 3%, maturity of five years and are generally identical in every respect except that bond A is an option-free bond, bond B is callable in two years and bond C is putable in two years. The yield curve is currently flat.

If the yield curve becomes upward sloping, the bond *least likely* to have the highest price impact would be:

- A) Bond B
 - B) Bond A
 - C) Bond C
-

Company Isla has a four-year, 6.5% bond that is callable under the following schedule:

- 102 in one year's time
- 101 in two years' time
- 100 in three years' time

The binomial interest rate assuming a 10% rate volatility is shown in Exhibit 1.

At each of the nodes:

F = the value of the bond obtained by applying the backward induction process (i.e., the expected PV of *future* cash flows from the bond)

C = the coupon received at the time of the node

V = For the call price depending on whether or not the company is likely to call the bond

Exhibit 1: Binomial Interest Rate Tree

T0

N
3.500%
V=103.94

Question #54 - 57 of 98

Question ID: 1473516

Which of the following represent the correct values that should be within the tree in the places marked by A and B?

- A) A = 99.041 B = 100.000
 - B) A = 99.041 B = 100.315
 - C) A = 100.000 B = 100.000
-

Question #55 - 57 of 98

Question ID: 1473517

Which of the following represent the correct value that should be within the tree in the place marked by D?

- A) 102.000.
 - B) 101.723.
 - C) 101.000.
-

Question #56 - 57 of 98

Question ID: 1473518

Which of the following is *most* accurate regarding the use of a binomial tree to calculate the option adjusted spread (OAS) of bonds with embedded options?

- A) The binomial tree can be used to calculate the OAS of a callable corporate bond but not a mortgage backed security (MBS), as the MBS does not contain an option.
 - B) The spot rate curve cannot be used to calculate the OAS of a callable corporate bond but can be used for a mortgage backed security (MBS).
 - C) The binomial tree can be used to calculate the OAS of a callable corporate bond but not a mortgage backed security (MBS), as the MBS value is path dependent.
-

Question #57 - 57 of 98

Question ID: 1473519

Which of the following represent the correct value that should be within the tree in the place marked by G?

- A) 96.352.
 - B) 102.000.
 - C) 102.576.
-

Question #58 of 98

Question ID: 1473508

Joseph Dentice, CFA is evaluating three bonds. All three bonds have a coupon rate of 3%, maturity of five years and are generally identical in every respect except that bond A is an option-free bond, bond B is callable in two years and bond C is putable in two years.

If interest rates increase, the duration of which bond is *most likely* to decrease?

- A) Bond A.
 - B) Bond C.
 - C) Bond B.
-

Question #59 of 98

Question ID: 1473466

Suppose that the value of an option-free bond is equal to 100.16, the value of the corresponding callable bond is equal to 99.42, and the value of the corresponding putable bond is 101.72. What is the value of the call option?

- A) 0.74.
- B) 0.64.
- C) 0.21.

Question #60 of 98

Question ID: 1473489

Bill Moxley, CFA is evaluating three bonds for inclusion in fixed income portfolio for one of his pension fund clients. All three bonds have a coupon rate of 3%, maturity of five years and are generally identical in every respect except that bond A is an option-free bond, bond B is callable in two years and bond C is putable in two years. The yield curve is currently flat.

If the yield curve becomes downward sloping, the bond with the highest price impact is *least likely* to be:

- A) Bond C
- B) Bond B
- C) Bond A

Dawn Adams, CFA, along with her recently hired staff, have responsibilities that require them to be familiar with backward induction methodology as it is used with a binomial valuation model. Adams, however, is concerned that some of her staff, particularly those not enrolled in the CFA program, are a little weak in this area. To assess their understanding of the binomial model and its uses, Adams presented her staff with the first two years of the binomial interest rate tree for an 8% annually compounded bond (shown below). The forward rates and the corresponding values shown in this tree are based on an assumed interest rate volatility of 20%.

A member of Adams' staff has been asked to respond to the following:

Question #61 - 64 of 98

Question ID: 1586248

Compute V_{1L} , the value of the bond at node 1L.

- A) \$95.99.
- B) \$103.58.
- C) \$101.05.

Question #62 - 64 of 98

Question ID: 1586249

Compute V_0 , the value of the bond at node 0.

- A) \$104.76.
 - B) \$99.07.
 - C) \$101.35.
-

Question #63 - 64 of 98

Question ID: 1586250

Assume that the bond is puttable in one year at par (\$100) and that the put will be exercised if the computed value is less than par. What is the value of the puttable bond?

- A) \$103.04.
 - B) \$95.38.
 - C) \$105.17.
-

Question #64 - 64 of 98

Question ID: 1586251

Assume that the bond is puttable in one year at par (\$100) and that the put will be exercised if the computed value is less than par. What is the value of the put option?

- A) \$0.42.
 - B) \$1.86.
 - C) \$3.70.
-

Question #65 of 98

Question ID: 1473493

Mary Pierce, CFA, has just joined The James Group as a fixed income security analyst. Pierce has taken over for Katy Williams, who left The James Group to start her own investment firm. Pierce has been reviewing Williams's files, which include data on a number of securities that Williams had been reviewing.

The first file had information on several different asset-backed securities. A summary schedule that Williams had prepared is shown in Exhibit 1.

Exhibit 1: Summary Schedule

Security	Rating	Nominal Spread (bp)
GG Auto Loans	AA	124
KK Auto Loans	AA	118
CC Credit Card Receivables	AA	136
HH Home Equity Loans	AA	168
LL Home Equity Loans	AA	174

The second file included the following schedule of information relating to a specific CMO that Williams had been considering. Exhibit 2 reflects the results of a Monte Carlo simulation based on 15% volatility of interest rates. This security is still available, and Pierce needs to evaluate the investment merit of any or all of the listed tranches.

Exhibit 2: Monte Carlo Simulation Based on 15% Interest Rate Volatility

Tranche	Par Amount (\$ million)	OAS (bp)	Z-Spread (bp)	Effective Duration (years)
PAC A	75.0	40	40	1.5

PAC B	40.0	43	95	4.2
PAC C	25.0	65	117	5.0
PAC D	50.0	72	140	7.9
Support S	100.0	51	142	11.8

A third file contained notes Williams had taken at a seminar a couple of months ago on valuing various types of asset-backed and mortgage-backed securities. These notes included the following comments that Pierce found interesting:

"Cash flow yield (CFY) is one method of valuing mortgage-backed securities. An advantage of the CFY is that it does not rely on any specific prepayment assumptions. An important weakness of CFY is the assumption that interim cash flows will be reinvested at the CFY. This is rarely true for mortgage-backed securities."

"Cash flow duration is similar to effective duration, but its weakness is that it fails to fully account for changes in prepayment rates as cash flow yields change. Empirical duration suffers two disadvantages as a measure of interest rate exposure: reliance on theoretical formulas and reliance on historical pricing data that may not exist for many mortgage-backed securities."

"The recent increase in the default rate for subprime adjustable rate mortgages can be traced to the structure of these loans. The negative amortization feature of these loans basically gave the borrower an at-the-money call option on their property. Once the property decreased in value, this call option was worthless, and the borrower had no incentive to make any additional payments."

The OAS in Exhibit 2 *most likely* reflect:

- A) simple spreads over the Treasury yield curve.
- B) average spreads over the Treasury spot rate curve.
- C) average spreads over the Treasury yield curve.

Question #66 of 98

Question ID: 1482980

Using the following interest rate tree, what is the value of a callable bond that has two years remaining to maturity, a call price of 99, and a 2.50% coupon rate? Assume that the call option can be exercised at $t=1$ year from now.

	3.80%
3.18%	
	2.61%

- A) 99.21.
- B) 98.25.
- C) 98.65.

Question #67 of 98

Question ID: 1473551

The primary benefit of owning a convertible bond over owning the common stock of a corporation is the:

- A) bond has more upside potential.
- B) bond has lower downside risk.
- C) conversion premium.

Question #68 of 98

Question ID: 1473476

For a putable bond, callable bond, or putable/callable bond, the nodal-decision process within the backward induction methodology of the interest rate tree framework requires that at each node the possible values will:

- A) not be higher than the call price or lower than the put price.
 - B) include the face value of the bond.
 - C) be, in number, two plus the number of embedded options.
-

Question #69 of 98

Question ID: 1473486

As the volatility of interest rates increases, the value of a callable bond will:

- A) rise.
 - B) decline.
 - C) rise if the interest rate is below the coupon rate, and fall if the interest rate is above the coupon rate.
-

Question #70 of 98

Question ID: 1473500

Sharon Rogner, CFA is evaluating three bonds for inclusion in fixed income portfolio for one of her pension fund clients. All three bonds have a coupon rate of 3%, maturity of five years and are generally identical in every respect except that bond A is an option-free bond, bond B is callable in two years and bond C is putable in two years. Rogner computes the OAS of bond A to be 50bps using a binomial tree with an assumed interest rate volatility of 15%.

If Rogner revises her estimate of interest rate volatility to 20%, the computed OAS of Bond B would *most likely* be:

- A) lower than 50bps.
 - B) equal to 50bps.
 - C) higher than 50bps.
-

Question #71 of 98

Question ID: 1473504

An analyst has constructed an interest rate tree for an on-the-run Treasury security. The analyst now wishes to use the tree to calculate the convexity of a callable corporate bond with maturity and coupon equal to that of the Treasury security. The usual way to do this is to calculate the option-adjusted spread (OAS):

- A) compute the convexity of the Treasury security, and add the OAS.
 - B) compute the convexity of the Treasury security, and divide by (1+OAS).
shift the Treasury yield curve, compute the new forward rates, add the OAS to those
 - C) forward rates, enter the adjusted values into the interest rate tree, and then use the usual convexity formula.
-

Question #72 of 98

Question ID: 1508673

Patrick Wall is a new associate at a large international financial institution. His boss, C.D. Johnson, is responsible for familiarizing Wall with the basics of fixed income investing. Johnson asks Wall to evaluate the two otherwise identical bonds shown in Table 1. The callable bond is callable at 100 and exercisable on the coupon dates only.

Wall is told to evaluate the bonds with respect to duration and convexity when interest rates decline by 50 basis points at all maturities over the next six months.

Johnson supplies Wall with the requisite interest rate tree shown in Figure 1. Johnson explains to Wall that the prices of the bonds in Table 1 were computed using the interest rate lattice. Johnson instructs Wall to try and replicate the information in Table 1 and use his analysis to derive an investment decision for his portfolio.

Table 1 Bond Descriptions

	Non-callable Bond	Callable Bond
Price	\$100.83	\$98.79
Time to Maturity (years)	5	5
Time to First Call Date	--	0
Annual Coupon	\$6.25	\$6.25
Interest Payment	Semi-annual	Semi-annual
Yield to Maturity	6.0547%	6.5366%
Price Value per Basis Point	428.0360	--

Figure 1

									15.44%
								14.10%	
							12.69%		12.46%
						11.85%		11.38%	
					9.75%		10.25%		10.05%
				8.95%		9.57%		9.19%	
			7.91%		7.88%		8.28%		8.11%
		7.35%		7.23%		7.74%		7.42%	
	6.62%		6.40%		6.37%		6.69%		6.54%
6.05%		5.95%		5.85%		6.25%		5.99%	
	5.36%		5.17%		5.15%		5.40%		5.28%
		4.81%		4.73%		5.05%		4.83%	
			4.18%		4.16%		4.36%		4.26%
				3.82%		4.08%		3.90%	
					3.37%		3.52%		3.44%
						3.30%		3.15%	
							2.84%		2.77%
								2.54%	
									2.24%
Years	0.5	1.0	1.5	2.0	2.5	3.0	3.5	4.0	4.5

Given the following relevant part of the interest rate tree, the value of the callable bond at node A is *closest* to:

		3.44%
A	3.15%	
		2.77%

- A) \$101.53.
- B) \$103.56.
- C) \$100.00.

Natalia Berg, CFA, has estimated the key rate durations for several maturities in three of her \$25 million bond portfolios, as shown in Exhibit 1.

Exhibit 1: Key Rate Durations for Three Fixed-Income Portfolios

Key Rate Maturity	Portfolio 1	Portfolio 2	Portfolio 3
2-year	2.45	0.35	1.26
5-year	0.20	0.40	1.27
10-year	0.15	4.00	1.23
20-year	<u>2.20</u>	<u>0.25</u>	<u>1.24</u>
Total	5.00	5.00	5.00

At a fixed-income conference in London, Berg hears a presentation by a university professor on the increasing use of the swap rate curve as a benchmark instead of the government bond yield curve. When Berg returns from the conference, she realizes she has left her notes from the presentation on the airplane. However, she is very interested in learning more about whether she should consider using the swap rate curve in her work.

As she tries to reconstruct what was said at the conference, she writes down two advantages to using the swap rate curve:

- Statement 1: The swap rate curve typically has yield quotes at 11 maturities between 2 and 30 years. The U.S. government bond yield curve, however, has fewer on-the-run issues trading at maturities of at least two years.
- Statement 2: Swap curves across countries are more comparable than government bond curves because they reflect similar levels of credit risk.

Berg also estimates the nominal spread, Z-spread, and option-adjusted spread (OAS) for the Steigers Corporation callable bonds in Portfolio 2. The OAS is estimated from a binomial interest rate tree. The results are shown in Exhibit 2.

Exhibit 2: Spread Measures for Steigers Corporation Callable Bonds

	Spread Measure	Benchmark
Nominal spread	25 basis points	Steigers Corp yield curve
Z-spread	35 basis points	Steigers Corp spot rate curve
OAS	-20 basis points	Steigers Corp spot rate curve
Nominal spread	120 basis points	Treasury yield curve
OAS	40 basis points	Treasury spot rate curve

Berg determines that to obtain an accurate estimate of the effective duration and effective convexity of a callable bond using a binomial model, the specified change in yield (i.e., Δy) must be equal to the OAS.

Berg also observes that the current Treasury bond yield curve is upward sloping. Based on this observation, Berg forecasts that short-term interest rates will increase.

Question #73 - 76 of 98

Question ID: 1586263

Are the two observations Berg writes down after the fixed income conference advantages to using the swap rate curve as a benchmark instead of a government bond curve?

- A) Only Statement 1 is an advantage.
 - B) Both statements are advantages.
 - C) Only Statement 2 is an advantage.
-

Question #74 - 76 of 98

Question ID: 1586264

If the spot-rate curve experiences a parallel downward shift of 50 basis points:

- A) Portfolio 1 will experience the best price performance.
 - B) all three portfolios will experience the same price performance.
 - C) Portfolio 3 will experience the best price performance.
-

Question #75 - 76 of 98

Question ID: 1586265

If the 5- and 10-year key rates increase by 20 basis points, but the 2- and 20-year key rates remain unchanged:

- A) Portfolio 2 will experience the best price performance.
 - B) all three portfolios will experience the same price performance.
 - C) Portfolio 1 will experience the best price performance.
-

Question #76 - 76 of 98

Question ID: 1586266

Is Berg correct about the specified change in yield needed to obtain an accurate estimate of the effective duration and effective convexity of a callable bond using a binomial model?

- A) No, because the specified change in yield can be larger than, smaller than, or equal to the OAS.
 - B) No, because the specified change in yield must be larger than the option-adjusted spread (OAS).
 - C) No, because the specified change in yield must be smaller than the OAS.
-

Question #77 of 98

Question ID: 1473513

Joseph Dentice, CFA is evaluating three bonds. All three bonds have a coupon rate of 3%, maturity of five years and are generally identical in every respect except that bond A is an option-free bond, bond B is callable at any time at par and bond C is puttable at any time at par. Yield curve is currently flat at 3%.

The bond *least likely* to have the highest one-sided down-duration is:

- A) Bond C.
 - B) Bond B.
 - C) Bond A.
-

Question #78 of 98

Question ID: 1473502

An analyst has constructed an interest rate tree for an on-the-run Treasury security. The analyst now wishes to use the tree to calculate the duration of the Treasury security. The usual way to do this is to estimate the changes in the bond's price associated with a:

- A) parallel shift up and down of the forward rates implied by the binomial model.
 - B) shift up and down in the current one-year spot rate all else held constant.
 - C) parallel shift up and down of the yield curve.
-

Question #79 of 98

Question ID: 1473467

Which of the following is equal to the value of the puttable bond? The puttable bond value is equal to the:

- A) option-free bond value plus the value of the put option.
 - B) callable bond plus the value of the put option.
 - C) option-free bond value minus the value of the put option.
-

Question #80 of 98

Question ID: 1473485

As the volatility of interest rates increases, the value of a puttable bond will:

- A) rise.
 - B) rise if the interest rate is below the coupon rate, and fall if the interest rate is above the coupon rate.
 - C) decline.
-

Question #81 of 98

Question ID: 1473540

What is the market conversion price of a convertible security?

- A) The value of the security if it is converted immediately.
 - B) The price that an investor pays for the common stock in the market.
 - C) The price that an investor pays for the common stock if the convertible bond is purchased and then converted into the stock.
-

Question #82 of 98

Question ID: 1473477

A puttable bond with a 6.4% annual coupon will mature in two years at par value. The current one-year spot rate is 7.6%. For the second year, the yield volatility model forecasts that the one-year rate will be either 6.8% or 7.6%. The bond is puttable in one year at 99. Using a binomial interest rate tree, what is the current price?

- A) 98.190.
 - B) 98.885.
 - C) 98.246.
-

Question #83 of 98

Question ID: 1473505

A CFA charter holder observes a 12-year 7 $\frac{3}{4}$ percent semiannual coupon bond trading at 102.9525. If interest rates *rise* immediately by 50 basis points the bond will sell for 99.0409. If interest rates *fall* immediately by 50 basis points the bond will sell for 107.0719. What are the bond's effective duration (ED) and effective convexity (EC).

- A) ED = 7.801, EC = 80.73.
 - B) ED = 8.031, EC = 2445.120.
 - C) ED = 40.368, EC = 7.801.
-

Question #84 of 98

Question ID: 1473552

How do the risk-return characteristics of a newly issued convertible bond compare with the risk-return characteristics of ownership of the underlying common stock? The convertible bond has:

- A) higher risk and higher return potential.
 - B) lower risk and lower return potential.
 - C) lower risk and higher return potential.
-

Question #85 of 98

Question ID: 1473480

Using the following binomial interest rate tree, calculate the value of a two-year, 2.5% putable bond. The American style embedded put option can be exercised anytime and has a strike price of 99. The value is *closest* to:

	3.75%
3.175%	
	2.665%

- A) 97.92.
 - B) 99.00.
 - C) 98.75.
-

Question #86 of 98

Question ID: 1473487

On a given day, a bond with a call provision rose in value by 1%. What can be said about the level and volatility of interest rates?

- A) The only possible explanation is that level of interest rates fell.
 - B) A possibility is that the level of interest rates remained constant, but the volatility of interest rates rose.
 - C) A possibility is that the level of interest rates remained constant, but the volatility of interest rates fell.
-

Question #87 of 98

Question ID: 1473534

For a convertible bond, which of the following is *least* accurate?

- A) The issuer can decide when to convert the bonds to stock.

- The conversion ratio times the price per share of common stock is a lower limit on
- B)** the bond's price.
- C)** A convertible bond may be putable.
-

Question #88 of 98

Question ID: 1473499

Sharon Rogner, CFA is evaluating three bonds for inclusion in fixed income portfolio for one of her pension fund clients. All three bonds have a coupon rate of 3%, maturity of five years and are generally identical in every respect except that bond A is an option-free bond, bond B is callable in two years and bond C is putable in two years. Rogner computes the OAS of bond A to be 50bps using a binomial tree with an assumed interest rate volatility of 15%.

If Rogner revises her estimate of interest rate volatility to 10%, the computed OAS of Bond B would *most likely* be:

- A)** lower than 50bps.
- B)** equal to 50bps.
- C)** higher than 50bps.
-

Question #89 of 98

Question ID: 1473483

A callable bond with an 8.2% annual coupon will mature in two years at par value. The current one-year spot rate is 7.9%. For the second year, the yield-volatility model forecasts that the one-year rate will be either 6.8% or 7.6%. The call price is 101. Using a binomial interest rate tree, what is the current price?

- A)** 100.279.
- B)** 100.558.
- C)** 101.000.
-

Question #90 of 98

Question ID: 1473469

For a callable bond, the value of an embedded option is the price of the option-free bond:

- A)** minus the price of a callable bond of the same maturity, coupon and rating.
- B)** plus the price of a callable bond of the same maturity, coupon and rating.
- C)** plus the risk-free rate.
-

Patrick Wall is a new associate at a large international financial institution. Wall has recently completed graduate school with a Master's degree in finance, and is also currently a CFA Level I candidate. His previous work experience includes three years as a credit analyst at a small retail bank. Wall's new position is as the assistant to the firm's fixed income portfolio manager. His boss, Charles Johnson, is responsible for getting Wall familiar with the basics of fixed income investing. Johnson asks Wall to evaluate the bonds shown in Table 1. The bonds are otherwise identical except for the call feature present in one of the bonds. The callable bond is callable at par and exercisable on the coupon dates only.

Table 1: Bond Descriptions

	Non-Callable	Callable Bond
Price	\$100.83	\$98.79
Time to Maturity (years)	5	5
Time to First Call Date	--	0

Annual Coupon	\$6.25	\$6.25
Interest Payment	Semi-annual	Semi-annual
Yield to Maturity	6.0547%	6.5366%
Price Value per Basis Point	428.0360	--

Question #91 - 94 of 98

Question ID: 1586253

Johnson asks Wall to compute the value of the call option. Using the given information what is the value of the embedded call option?

- A) \$0.00.
- B) \$1.21.
- C) \$2.04.

Question #92 - 94 of 98

Question ID: 1586254

Wall is a little confused over the relationship between the embedded option and the callable bond. How does the value of the embedded call option change when interest rate volatility increases? The value:

- A) may increase or decrease.
- B) increases.
- C) decreases.

Question #93 - 94 of 98

Question ID: 1586255

Wall wonders how the value of the callable bond changes when interest rate volatility increases. How will an increase in volatility affect the value of the callable bond? The value:

- A) may increase or decrease.
- B) decreases.
- C) increases.

Question #94 - 94 of 98

Question ID: 1586256

Wall now turns his attention to the value of the embedded call option. How does the value of the embedded call option react to an increase in interest rates? The value of the embedded call is *most likely* to:

- A) increase.
- B) remain the same.
- C) decrease.

Mike Duffle has been asked to evaluate the bonds of Hardin, Inc. The specific issue Duffle is considering has an 8% annual coupon and matures in two years. The bonds are currently callable at 101, and beginning in six months, they are callable at par. Bratton Corporation, Hardin's competitor, also has bonds outstanding which are identical to Hardin's except that they are not callable. Duffle believes the AA rating of both bonds is an accurate reflection of their credit risk. Duffle is wondering if the Bratton bonds might be a better investment than the Hardin bonds. Assume that the following 1-year interest rate tree is used to value bonds with a maturity of up to three years (this tree assumes interest rate volatility of 10%).

Today	Year 1	Year 2
		9.324%
	8.530%	
7.250%		7.634%
	6.983%	
		6.250%

Also, assume that the appropriate spot rates for securities maturing in one, two, and three years are 7.25%, 7.5%, and 7.80%, respectively.

Diffle believes he should begin his analysis with the option-free Bratton bonds. He decides to consider two different approaches to valuing the Bratton Bonds—one that uses the current spot rate curve and another that uses the interest rate tree given above.

For the next step in his analysis, Diffle has decided to calculate the value of the Hardin bonds using the interest rate tree. His assumption is that the bond will be called at any node of the tree where the calculated value exceeds the call price. Diffle summarizes the results of his bond valuation analysis in a memo to his supervisor, Luke Puldo. In this memo, Diffle makes the following statements:

- The value of the option embedded in the Hardin bonds can be derived by simply subtracting the interest rate tree value of the Hardin bonds from the interest rate tree value of the Bratton bonds.
- I am concerned that the 10% volatility assumption used to develop the interest rate tree might be too low. A higher volatility assumption would result in a lower value for the Hardin bonds.

After reviewing Diffle's analysis, Puldo notes that Diffle has not included any information on the option adjusted spread (OAS) for the Hardin bonds. Puldo suggests that Diffle should evaluate the OAS in order to get an idea of the liquidity risk of the Hardin bonds. Diffle counters that the OAS may not be very informative in this case, since he is uncertain as to the reliability of the interest rate volatility assumption.

To finish his analysis, Diffle would like to use his binomial model to evaluate the interest rate risk of both the Hardin bonds and the Bratton bonds. Diffle has shocked interest rates by 25 basis points throughout the interest rate tree he has been using to value the two bond issues. Using the new rates, Diffle has calculated values for the bonds assuming a 25-basis-point increase or decrease in rates. He plans to use these values as inputs into the following formulas for duration and convexity:

$$\text{duration} = \frac{V_- - V_+}{2 \times V_0 \times \Delta y} \quad \text{convexity} = \frac{V_+ + V_- - 2V_0}{2 \times V_0 \times (\Delta y)^2}$$

Question #95 - 98 of 98

Question ID: 1473521

Puldo still believes that Diffle must include the OAS for the Hardin bonds in his report. Puldo points out that a proper benchmark is critical to any OAS analysis. Which of the following statements regarding benchmark interest rates and OAS is *most* accurate? Since liquidity risk is a critical issue, the OAS calculation for the Hardin bonds should:

- A) use on-the-run U.S. Treasury rates as a benchmark in order to isolate the credit risk of the Hardin bonds.
- B) use on-the-run interest rates for other callable Hardin bonds as a benchmark in order to isolate the liquidity risk of the 2-year bond issue.
- C) be based on a benchmark that has no credit risk.

Question #96 - 98 of 98

Question ID: 1473522

Which of the following statements is *most* accurate regarding Diffle's calculation of duration and convexity?

- A) The duration estimate will be inaccurate since it does not account for any change in cash flows due to the call option embedded in the Hardin bond.

The estimates for both duration and convexity will be inaccurate because the OAS
B) was not estimated again after the rate shock.

The duration estimate for the Bratton bonds will reflect the projected percentage
C) change in price for a 100-basis-point change in interest rates.

Question #97 - 98 of 98

Question ID: 1473523

Puldo notes that the duration estimate for the two bonds is not directly comparable.

Assuming that the underlying option is at- or near-the-money, the duration of one of the bonds will be lower than the other one.

Which of the following *most* accurately critiques the OAS discussion between Diffle and Puldo? Puldo is:

- A)** correct that the OAS will provide insight into the liquidity risk of the Hardin bonds, and Diffle is correct that different volatility assumptions would change the OAS.
 - B)** incorrect that the OAS will provide insight into the liquidity risk of the Hardin Bonds, but Diffle is correct that different volatility assumptions would change the OAS.
 - C)** correct that the OAS will provide insight into the liquidity risk of the Hardin Bonds, but Diffle is incorrect since OAS implicitly adjusts for the volatility of interest rates.
-

Question #98 - 98 of 98

Question ID: 1473524

Puldo notes that the duration estimate for the two bonds is not directly comparable.

Assuming that the underlying option is at- or near-the-money, the duration of one of the bonds will be lower than the other one.

Indicate whether the statements made by Diffle in his memo regarding the value of the embedded option and the effect of the volatility assumption are correct.

- A)** Both statements are correct.
- B)** Only the statement regarding the effect of the volatility assumption is correct.
- C)** Only the statement regarding the value of the embedded option is correct.
